Berkeley, California 94710-2721

Subject: Baker Beach 1, 2 Landfill Removal Project
Field Investigation Report

Dear Bob:

As promised in our meeting with you and Ram Ramanujam on May 24, 2006, the Presidio Trust (Trust) is transmitting the *Field Investigation Report, Baker Beach Disturbed Areas 1, 1A, 2 and 2A, Presidio of San Francisco, California*. This report was prepared by MACTEC Engineering and Consulting, Inc. (MACTEC) with contributions by URS Corporation (URS), National Park Service (NPS) staff, and SOHA Engineers, Inc. (SOHA). The report includes the following important components:

1. Geotechnical sampling, laboratory testing and engineering analysis evaluating the material strengths and stability of the coastal bluffs and landfill deposits now, during landfill removal operations and post-remediation.
2. An extensive Cultural Resource Baseline and Impact Assessment prepared by URS with assistance from NPS personnel. This assessment documents the historic features in the landfill area that contribute to the Presidio's National Historic Landmark designation, and includes recommendations for avoiding and/or mitigating construction impacts on the historic resources.
3. A baseline structural inspection of the historic coastal batteries prepared by SOHA documenting the current conditions of the coastal fortifications and providing recommendations for monitoring the fortifications during the remediation work.

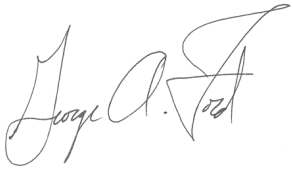
This work shows that the Baker Beach 1 and 2 project can protect human and ecological receptors from waste effects and preserve and enhance the important historical resources located in the work area.

We have also attached two additional items:

1. A searchable PDF file of the report on CD, and
2. Preliminary drawings showing the expected excavation limits and waste quantities. These drawings will be finalized and included in the Remedial Action Plan (RAP) that is now in preparation.

We look forward to meeting with you to discuss your comments and thoughts on this work. We will contact you shortly to set a convenient date for this meeting. In the meantime, please call if you have any questions.

Sincerely,



George Ford
The Presidio Trust

Enclosure: 1) *Field Investigation Report, Baker Beach Disturbed Areas 1 and 2, Presidio of San Francisco, California*
2) Searchable PDF on CD, *Field Investigation Report, Baker Beach Disturbed Areas 1 and 2, Presidio of San Francisco, California*
3) Preliminary excavation drawings from the RAP

CC: Ram Ramanujam, DTSC Sacramento

1.0 INTRODUCTION

This Field Investigation Report has been prepared by MACTEC Engineering and Consulting, Inc. (MACTEC) on behalf of the Presidio Trust (Trust) to present the results of field investigation activities at four Baker Beach Disturbed Areas (BBDAs; BBDA-1, BBDA-1A, BBDA-2, and BBDA-2A) located along the coastal area of the Presidio of San Francisco, California (Presidio; Figure 1). This work was performed under the direction of the Trust, in collaboration with the National Park Service (NPS) environmental, cultural resources, natural resources personnel, and other Trust contractors, and under the regulatory oversight of the Department of Toxic Substances Control (DTSC).

One remedy being considered in the Remedial Action Plan (RAP; *MACTEC, 2004b* [final RAP in preparation]) for BBDAs is excavation and clean closure. Although the Army labeled the BBDAs as "disturbed areas" when the sites were initially investigated (*Dames and Moore, 1997)*, they are actually soil and debris deposits (landfills) created by dumping truckloads of debris on top of and over the edge of coastal bluff above the Pacific Ocean. Historically-significant coastal artillery batteries and associated earthworks occupy the top of these coastal bluffs along most of the area where the landfills occur. Implementation of an excavation remedy is complicated not only by batteries and various roads and trails located on the bluff top that limit construction access but also by the inherent slope instability that is part of the natural coastal erosion processes. The goal of the remedy is to remove landfill debris from the bluff-top and cliff-side to restore the area to its native condition without further destabilizing materials in these areas, accelerating erosion, or adversely impacting historically significant features.

The purpose of the current field investigation program described herein is to address site characterization data gaps identified during preparation of the RAP, provide geotechnical recommendations for the remedial design to mitigate possible adverse effects during construction and after the debris has been removed, and delineate significant historic resources and assess their structural condition to avoid adverse impacts to these resources during and after construction.

Work plans for proposed field activities were prepared late 2004 and early 2005, in collaboration with DTSC, Trust, and NPS, and field work was performed February 2005 through February 2006. This Field Investigation Report presents and evaluates the results of this and previous field investigations and provides recommendations for preparation of an excavation remedial design to mitigate adverse effects during and after implementation of the remedy to historical features and slope stability.

1.1 Report Organization

This Field Investigation Report is organized as follows:

- **Section 2 – Background**: Discusses previous investigations, and the sampling plans for the current investigations.
- **Section 3 – Methods of Investigation:** Discusses the general field methods, sampling techniques, and laboratory analyses used for the BBDA sites.
- **Section 4 – Regional Geology:** Presents an overview of the regional geologic, seismic, and hydrogeologic setting of the project sites.
- **Section 5 – Potential Geologic Hazards:** Discusses the potential geologic hazards at the study area.
- **Section 6 – Site Conditions:** Discusses surface and subsurface conditions, including site specific geology, soils, and groundwater.

- **Section 7 – Slope Stability Analyses:** Presents the input parameters, methodologies, and results of the slope stability analyses.
- **Section 8 – Conclusions and Recommendations:** Provides a discussion of geotechnical, environmental, and remediation issues; presents recommendations for construction planning, earthwork, and other pertinent inputs to remedial design.
- **Section 9 – References:** References listed in the main body of the text.
- **Tables:** Provide summaries of exploration points, chemical data, groundwater measurements, and geologic and seismic sources.
- **Figures:** Shows site locations, regional geology and the study area geologic map, and presents analytical results.
- **Appendices:**
  - Appendix A: Exploratory trench logs, test pit logs, and boring logs
  - Appendix B: Cultural Baseline and Impact Assessment and West Battery & Fort Scott Endicott Batteries – Construction, Evolution, and Modifications
  - Appendix C: Analytical and Geotechnical Laboratory Test Results, and Data Validation Reports
  - Appendix D: Geotechnical Slope Stability Analysis
  - Appendix E: Draft Geotechnical Memorandum Material Properties
  - Appendix F: Baseline Structural Inspection (SOHA Report)
  - Appendix G: Geophysical Mapping
  - Appendix H: Beach Debris Survey
  - Appendix I: Selected Photographs
  - Appendix J: Groundwater Sample Forms and Seep Calculations
  - Appendix K: Merchant Road Realignment Geotechnical Investigations
  - Appendix L: Scatter Plots
  - Appendix M: Disk with PDF of Laboratory Analytical Results.

2.0 BACKGROUND

2.1 Previous Investigations

A previous remedial investigation (RI) by Dames & Moore in 1997, which included an examination of aerial photographs dating from 1946 to 1986 and on-site visual inspections, identified three "disturbed areas" where buried refuse is present in the vicinity of Baker Beach. Fill material, including artificial fill, debris fill, and landfill material, was reported to be deposited at the three areas intermittently from 1946 to 1973. At the time of the RI report, it was unknown if fill was deposited earlier than 1946 (*Dames & Moore, 1997*). Artificial fill at the sites was characterized by random mixtures of soil, chert, and serpentinite fragments. Debris fill consists of building debris, such as brick, concrete, glass, and wood. Glass, ceramics, automotive parts, and metal containers are typically observed landfill material.

Subsequent to the RI, a fourth debris area, BBDA-2A was discovered in August 2000 on the basis of visual observation of mounded soil and a change in vegetation relative to surrounding areas. In 2003, topographic and geophysical surveys were conducted to delineate the areal and vertical extent of debris, and a bathymetric study was performed to evaluate the feasibility of water-side remedial operations. Using electromagnetic (EM) and global positioning system (GPS) survey tools, the purpose of the geophysical survey was to determine the maximum lateral extent of observed and shallow debris for planning purposes of the investigation.

Waste characterization of BBDA-2A, as well as further soil and waste sampling of BBDA-1A, were also conducted in 2003 and late 2004. Using surface and shallow hand auger sampling methods, the investigations evaluated roofing material and asbestos-containing soil and bedrock at these areas, and options for disposal and work safety mitigation. The results of the 2003 characterizations are presented in the *Interim Data Report, Baker Beach Disturbed Areas 1, 1A, 2, and 2A* (*MACTEC, 2003b*). Table 1 provides a summary of surface and subsurface field exploration for these previous investigations. The analytical results from previous investigations conducted in 2004 are included in this report. Appendix G presents geophysical mapping results.

2.2 Field Sampling Plans, Other Studies, and Interim Data Transmittals

The scope of work and methods for the 2005 field investigation was developed in the following Field Sampling Plans (FSPs) for the cultural, geotechnical, and environmental investigations:

- *Cultural Resource Investigation Field Sampling Plan* (Cultural Resource FSP), submitted January 2005 (*URS, 2005*)
- The *Geotechnical Field Sampling Plan* (Geotechnical FSP), submitted on May 2, 2005, including a previous addendum of March 2, and comments by DTSC on April 5, 2005 (*MACTEC, 2005e*)
- *Environmental Field Sampling Plan* (Environmental FSP), submitted on May 2, 2005, incorporating an earlier addendum of March 14, 2005, and comments by DTSC on April 5, 2005 (*MACTEC, 2005f*)
- *Additional Sampling to Fill Data Gaps, Baker Beach 1 and 2 Field Investigation, Presidio of San Francisco* (*Trust, 2006*)

DTSC reviewed and approved these FSPs. The Trust submitted an additional FSP, *Baker Beach Disturbed Areas 1 and 2, Additional Sampling West of Merchant Road* (*MACTEC, 2005g)*, to DTSC on

September 8, 2005 after review of information contained in a historical research report prepared by John Martini, *West Batteries and Fort Scott Endicott Batteries Construction, Evolution, and Modification (Martini, 2005; Appendix B)*. This report contained a photograph taken in 1967 that showed fill placed west of Merchant Road.

In conjunction with the above plans, the following two additional studies were performed. SOHA Engineers, San Francisco, California (SOHA) performed a structural evaluation of selected fortification structures (Battery Godfrey, Battery Boutelle, Battery Marcus Miller, and brick magazines 21, 22, 27, 28, and 29) to assess their structural integrity. MACTEC also performed a beach debris survey to assess debris material downslope of the landfill areas on the beach to assess the extent of debris that might have fallen from debris areas.

During implementation of the field investigation, several interim data transmittals were sent to DTSC that contained laboratory analytical and geotechnical test results *(MACTEC, 2005a, b, c, and d)*. A geotechnical technical memorandum was also prepared and sent to DTSC that presented the field sampling, evaluation of laboratory test results, and proposed input parameters for a geotechnical model *(MACTEC, 2005i)*. Information from this technical memorandum has been incorporated into this report and a copy can be found in Appendix E.

An overview of each FSP as well as the geotechnical memorandum, SOHA structural evaluation, and beach debris survey are further described below.

2.2.1 Cultural Resource Investigation Field Sampling Plan

The purpose of the Cultural Resource Investigation/Cultural Resource Baseline and Impact Assessment (CRI) FSP was to describe field exploration and sampling necessary to evaluate and develop plans to protect the cultural resources at the BBDAs during landfill removal operations (*URS, 2005*). The project area for the CRI was defined by the Area of Potential Effect (APE) shown on Figure 2 of the Cultural Resource Baseline and Impact Assessment Report presented in Appendix B.

These cultural resources include Batteries Marcus Miller, Godfrey, and Boutelle, as well as the structural elements of Battery West. Some of the features of these resources were partly obscured by vegetation and debris or were buried. As such, they could be vulnerable to impact from remediation activities including truck traffic, excavations and filling, and heavy equipment. Therefore, identification and characterization efforts were proposed to better delineate resources. Part of the scope of work included vegetation removal to expose landforms and historic features, which was performed from February 14 to 23, 2005, prior to the start of bird nesting. Figure 3 is an aerial photograph that was taken in March 2005 one month after vegetation was removed from the site. The CRI FSP was reviewed and approved by DTSC during a meeting held on February 28, 2005.

The CRI FSP proposed field activities included trenching and mapping concurrent with the geotechnical and environmental tasks as well as artifact identification, cataloging, and supplemental research of the four BBDAs. The result of these activities is documented in a CRI, prepared jointly by URS Corporation (URS), NPS personnel, and John Martini. The CRI provides specific information regarding cultural resources present in the study area and also provides an impact assessment and treatment recommendations to protect cultural resources during remediation.

2.2.2 Geotechnical Field Sampling Plan and Technical Memorandum

The goals of the Geotechnical FSP were to perform an evaluation of the slope stability in their current configuration, during construction, and following remediation, and to provide geotechnical

recommendations and design parameters to mitigate possible adverse effects during construction and after the waste has been removed. Specific Geotechnical FSP objectives were to obtain data to: (1) assess how the selected remedial action could affect the stability of historical gun battery emplacements at the site; (2) evaluate the stability of areas identified for use and staging of heavy equipment required to perform the remedial work; and (3) evaluate the stability of the debris areas that will be removed as part of the selected remedial action.

The geotechnical evaluation was designed to evaluate only short-term effects of the proposed remedial action on slope stability, i.e., until the native vegetation has been re-established as a natural form of slope protection, and did not include evaluation of the long-term effects of natural processes on the stability of the slopes and cultural resources at the site after the waste fill materials had been removed.

The geotechnical evaluation focused on the stability of the batteries, the stability of potential equipment and stockpile staging areas, and the stability of the remediated debris areas. Additional data and information to be evaluated as part of the study included:

- Construction details of the batteries;
- Configuration and stratigraphy of soil and rock units;
- Bedrock structural features and discontinuities;
- Geotechnical engineering properties of soil and bedrock;
- Seeps and groundwater conditions; and
- Equipment dimensions and loads.

The Geotechnical FSP proposed sampling locations (test pits and borings), the rationale for laboratory test frequency, and the approach taken for the slope stability analysis. DTSC approved the Geotechnical FSP during a meeting held on February 28, 2005, and requested that interim data transmittals be sent during data collection. In addition, prior to performing the slope stability modeling, DTSC requested that the Trust submit proposed input parameters for the model as well as an explanation as to how these parameters were derived.

Interim data transmittals were sent on April 25, May 24, June 1, and October 24 (*MACTEC, 2005a, b, c, and d*). The Trust submitted a Geotechnical Technical Memorandum to DTSC on September 21 that summarized and evaluated geotechnical laboratory test results and proposed input parameters for material properties of rock and soil in the study area (*MACTEC, 2005i*). The Geotechnical Technical Memorandum described the field sampling methods and geotechnical laboratory analyses, and detailed the statistical evaluation of published, observational, and laboratory data provided information for the slope stability analyses. The DTSC approved the proposed parameters in October 2005. The draft geotechnical material properties memorandum is presented with the laboratory information in Appendix E of this report.

2.2.3 Environmental Field Sampling Plan

Previous environmental sampling of the BBDAs was conducted by the Army as part of their RI work (*Dames & Moore, 1997*), and by MACTEC *(2003b*). The investigations performed by MACTEC in 2003 were conducted following procedures provided in environmental field sampling plans (*MACTEC, 2003a*) to characterize surface and relatively shallow soil and sediment. The Environmental and Additional Environmental FSPs (*MACTEC, 2005f and g*) were developed to address site characterization data gaps

identified by DTSC from their preliminary review of selected RAP chapters. The FSP also had the objective of better understanding the lateral and vertical extent of waste fill to assist in estimating quantities for costing remedial alternatives in the RAP.

DTSC had identified the following site characterization data gaps after reviewing MACTEC's Interim Data Report (*MACTEC, 2003b*):

- The presence and concentrations of contaminants present in both historic fill and waste fill around the batteries on the bluff top;
- The presence of ash and contaminants around a former incinerator facility at BBDA-1 (shown on Figure 2);
- The presence of contaminants around a former salvage/recycling facility south of BBDA-2;
- Depth of waste materials;
- The presence and concentration of contaminants in debris on portions of BBDA-2, Baker Beach, and Magazine 21;
- Confirmation of analytical results from previous surface water sampling of the seep at BBDA-1 and 2A; and
- Confirmation of analytical results from previous soil sampling of historic fill, native soils, and bedrock at BBDA-1, -2 and -2A.

A meeting was held on April 4, 2005 with DTSC to discuss how the above data gaps would be addressed, and DTSC approved the proposed work during this meeting.

2.3 Baseline Structural Evaluation

As part of the geotechnical study to evaluate potential adverse impacts to batteries on the coastal bluffs, SOHA performed a baseline structural evaluation to:

- Provide a baseline condition survey of the fortifications before landfill removal and as a basis for monitoring during construction.
- Assess the cause of existing cracks in Battery Boutelle (e.g., are they present as a result of slope instability).
- Assess whether it would be possible to transport waste from BBDA-1A over the top of Battery Marcus Miller.
- Recommend mitigation measures during construction, if required.

The scope of work for this evaluation was included in the Geotechnical FSP. Appendix F presents SOHA's report.

2.4 Beach Debris Surveys

MACTEC performed beach survey transects and GPS locations in 2005 to assess the location of selected and partially buried debris, and to collect information on sand burial records. Appendix H presents the

results of this study. In addition, as part of collecting additional environmental information to fill data gaps, MACTEC collected three samples of beach sand that were submitted for analysis. These samples were collected near large pieces of debris that had fallen onto the beach.

3.0 METHODS OF INVESTIGATION

Geotechnical, environmental, cultural resource, and structural studies were performed between February 2005 and February 2006 by:

- MACTEC (geotechnical and environmental investigations);
- URS (cultural resources assessment study) and Martini (historic research study of the Baker Beach area); and
- SOHA (battery structural study).

Trust, NPS, and URS provided technical review and field support; DTSC reviewed work plans and interim data transmittals, and provided regulatory oversight prior to and during implementation of the field plans.

The methods of investigation included literature review and analysis, field surface geologic and geophysical mapping, installation of subsurface borings, test pits and trenches, and collection of environmental and geotechnical samples for laboratory testing and analysis.

The following sections describe the purpose and methods employed during the investigations. Table 1 presents a comprehensive list of exploration and sampling points both prior to and including the 2005 field investigations.

3.1 Geologic Literature Review

Prior to performing geologic mapping, MACTEC performed a literature review to obtain and consolidate previous mapping, research, photography, and reports to use as a baseline and guide for collecting new information. The results of the literature review provide the basis for discussions of regional geology discussed in Section 3.0, and geologic hazards as discussed in Section 4.0. The following sources of information were reviewed as part of the literature review for relevance to the objectives of the study:

- Regional geologic studies as recorded on maps and in papers by governmental agencies included reports prepared by the U. S. Geological Survey (USGS), California Geological Survey (CGS, formerly California Division of Mines and Geology [CDMG]), and the U. S. Department of Agriculture (USDA).
- Specific geologic work pertaining to the Presidio and vicinity, as conducted by Shlocker (*1974*), Wahrhaftig (*1984*), and Elder (*2001*) along with reports prepared by Treadwell and Rollo (*2004*), and Erler and Kalinowski (*EKI, 2003*).
- Stereo-paired and oblique black and white historical aerial photos, taken in 1935 through 2001, were reviewed at the offices of Pacific Aerial Surveys located in Oakland, California, on January 28, 2005 (see list of photos in Section 9.0). Available historical aerial photos from Presidio archives were also reviewed.
- The NPS archivist provided as-built drawings of historical structures in the study area. These drawings provided information pertaining to historical subgrade and surface elevations adjacent to the fortification structures.

3.2 Geologic Mapping

The purpose of the geologic mapping was to delineate geologic units and fill deposits in the study area and to correlate geologic units with cultural features such as historic fill. As part of the slope stability evaluation, it was necessary to delineate the different geologic materials and to identify the presence of seeps, drainages, landslides, and geologic structural features.

Although several types of fill materials are present, the goal of the remediation is to excavate only materials that have chemicals of concern (COCs) above action levels. Historic fill is considered an historical resource, and as such, it is important to protect it during remediation. In addition, planned restoration includes planting native plants on serpentinite soils. Some bedrock areas have a thin veneer of weathered soil that would be required for planting, and as a result, it is also necessary to leave as much of this weathered soil in place as possible during remediation.

MACTEC conducted geologic mapping from February 22 to 25, 2005. Two field geologists, under supervision of a Certified Engineering Geologist (CEG), mapped the surface geology using base orthophotographic maps at a scale of 1 inch equals 100 feet and topographic maps at a scale of 1 inch equals 20 feet. Surficial soil units, bedrock units, and structural attitude data (bedding, shearing, and jointing) were documented in field books and plotted onto field maps. Where possible, elongate contacts (i.e., erosional scarps or basal geologic contacts) were mapped using GPS instrumentation.

Using GPS, the field geologists staked and located proposed test pits, test trenches, and boring locations. Trust, URS, and NPS natural and cultural resource specialists reviewed the proposed locations. Minor adjustments were made to the proposed FSP locations due to limited access and proximity to sensitive resources. The resulting geologic map is presented on Figure 2.

3.3 Beach Survey

The purpose of this study was to map beach debris to assess whether it would need to be removed and to collect sand samples to assess potential contamination in the beach area from fallen materials.

The investigation included a survey of beach debris and beach sand elevation. The beach survey entailed GPS mapping and photographic documentation of debris materials. The sand survey entailed measuring ground (sand) surface elevations at 10-foot intervals along one transect in each survey area. MACTEC conducted the investigation over one year with four surveys performed on February 19, 2004; May 10, 2004; September 14, 2004; and January 28, 2005. Appendix H presents the results of the beach surveys.

On May 13, 2005, three beach sand samples were collected for laboratory analysis to assess whether contamination is present in the beach area where the debris materials are present. MACTEC collected samples by removing the top 6 inches of sand and pressing a tube directly into soil from 0.5 to 1 foot below ground surface (bgs). Analytical results are presented and discussed in Section 6.2.

3.4 Test Pit Excavations

MACTEC performed test pit excavations using equipment suitable for flat and sloping terrain. The purpose of the test pits was to evaluate remedial area boundaries, depth of waste fill, and to collect samples to assess geotechnical parameters and environmental conditions. Appendix A2 contains the test pit logs. Test pit excavations in selected areas are further described below.

3.4.1 BBDA Test Pits

Test pit excavations in the vicinity of the BBDAs were conducted from April 6 to 21, 2005. Figures 2 and 3 show their locations.

AIS Construction (AIS), Santa Barbara, California excavated the test pits on slopes too steep for conventional excavators using a "Spyder" excavator (Model No. 52 "Kaiser Kuick Foss,") that is adapted to work on steep slopes. It is designed and used primarily for hillside logging and repair work (Appendix I contains photographs of the Spyder excavator). The equipment is also capable of moving materials on steep slopes during remedial-type activities. The Spyder accessed the disposal area slopes from parking lots on the bluff above BBDA-1 and BBDA-2, the coastal trail above BBDA-2, and the beach below BBDA-1 and BBDA-2A. It was lowered down the slope by a winch attached to a bulldozer.

MACTEC obtained soil and waste samples from the sidewalls and bottom of the test pits for both analytical and geotechnical testing, and collected undisturbed samples by pushing thin-walled Shelby tubes, brass liners, and stainless steel liners into the target strata. Grab samples were placed in bags and later transferred into sealed containers. Both NPS and Trust natural and cultural resource monitors were present during equipment ingress/egress and during excavation to monitor potential ground disturbance and to collect artifacts where present.

Test pits were typically less than 10 feet deep, and were entered only by qualified personnel after sloping back the sides of the excavations in accordance with the Health and Safety Plan. The deeper excavation pits, which extended as deep as around 21 feet, were logged from the surface and samples were obtained from the excavator bucket.

MACTEC's field geologist logged the test pits using the Unified Soil Classification System (USCS) or the Rock Properties Description of the International Society of Rock Mechanics, as appropriate. Logs were prepared at a scale of 1 inch equals 5 feet.

Test pit excavations were backfilled with excavation spoils after logging and sampling. Weed-free loose straw was placed over each test pit location and surrounding disturbed areas to minimize run-off and erosion of bare soil.

3.4.2 Merchant Road Test Pits

Four test pits were excavated along the proposed area for Merchant Road realignment. Three pits were located in a wooded area between Merchant Road and Lincoln Boulevard; the fourth pit was located near Battery Marcus Miller as part of a percolation test in a future Golden Gate Bridge, Highway and Transportation District (GGBHTD) parking lot.

The test pits were excavated to depths up to 6 feet. Representative bulk samples were collected for geotechnical lab analysis to support pavement structural design. The test pits were backfilled with excavation spoils.

Figure 2 shows the location of infiltration testing on an adjacent test location. The results of the infiltration testing are located in Section 6.2.5 of this report, and in a technical memorandum on Merchant Road realignment (*MACTEC, 2005j*) which is provided as Appendix K of this report.

3.4.3 Additional Investigation Test Pits

Four additional test pits were excavated on October 3 and 4, 2005 in an area between the Covered Way and Merchant Road, as shown on Figures 2 and 3, based on a review of a report by John Martini, *Cultural*

Resource Baseline and Impact Assessment (Appendix B). An aerial photograph taken in May 1967 shows fill placed west of Merchant Road and east of Battery Marcus Miller. Engineering/Remediation Resources Group, Inc. (ERRG), Concord, California excavated these pits under supervision of MACTEC to a depth of 6 feet or less using rubber-tired backhoes.

MACTEC collected representative grab samples for analytical testing to determine concentrations of COCs. MACTEC's field geologist visually logged the test pits, and noted fill, native soil, and bedrock conditions. Test pits were backfilled with excavation spoils.

3.4.4 Test Pit and Boring Location Survey

Soil boring and test pit locations were surveyed using a GPS. Data from the GPS instrument were downloaded in the office and used to create geographic information system (GIS) files on which the figures in this report are based.

3.5 Cultural Resource Investigation

Trenching was performed as part of the CRI to assess cultural and historic resources present that need to be protected during remediation.

In February 2005, vegetation was cleared from areas around the bluff-top fortifications prior to the start of the bird nesting season. URS and NPS performed surface mapping of the exposed cultural and historic features, and updated existing NPS cultural resource maps.

In April and May of 2005, ERRG excavated trenches for the cultural resource assessment at two locations (Figures 2 and 3). Seven trenches (Trenches 1, 2, 3, A, B, C, and D) were excavated in the parking lot between Battery Godfrey and BBDA-2 and -2A using a John Deere model 710 rubber-tired excavator. Three trenches were excavated on a cleared area between Battery Boutelle and Battery Marcus Miller (Trenches 4, 5, and E). Figures 2 and 3 show the trench locations. MACTEC's field geologist logged subsurface materials, including historical and waste fill, native soils, and bedrock in collaboration with URS and NPS personnel. Appendix A shows details and position of exploratory trenches for the cultural resource assessment. The CRI also presents trench logs (Appendix B).

3.6 Soil Borings

Soil borings were drilled to collect soil samples to assess geotechnical properties and environmental conditions. Three types of soil borings (hollow stem auger, hand auger, and direct-push) were implemented during the field investigation. Appendix A3 contains soil boring logs.

3.6.1 Hollow Stem Auger Borings

Gregg Drilling, Martinez, California, drilled hollow stem auger borings at selected sites. The purpose of these borings was to obtain undisturbed soil samples and blow count data. Gregg Drilling used truck-mounted equipment to advance 11 borings to depths ranging from 10.4 to 23.7 feet bgs. Clearheart Drilling, Santa Rosa, California, provided limited-access drilling equipment at three locations where ground conditions were too soft or access routes too narrow to use truck-mounted equipment. The limited-access borings were advanced to depths ranging from 13.6 to 25.5 feet bgs.

MACTEC's geologist logged the borings and obtained soil samples for visual classification and laboratory testing. Samples were obtained continuously using a standard penetration testing (SPT) split barrel sampler (2.0-inch outside diameter, 1-3/8-inch inside diameter) without liners, or a Modified

California split-barrel sampler (3.0-inch outside diameter, 2.43-inch inside diameter) lined with 6-inch-long brass tubes. Samples were extruded and quartered along the length of the tube by the geotechnical soils testing laboratory. Undisturbed soil samples were obtained by pushing a 3-inch diameter, thin-walled Shelby Tube using the hydraulic draw works on the drill rig.

The SPT and Modified California samplers were driven by 30-inch drops of a 140-pound above ground automatic trip hammer. The blow counts were recorded from driving the SPT sampler for the final 12 inches of an 18-inch drive, or to refusal. These SPT blow counts were converted to approximate SPT N-values using 1.2 as the conversion factor to account for the higher energy efficiency of the automatic trip hammer compared to the conventional rope-and-cathead method. The blow counts recorded from driving the Modified California sampler the final 12 inches of an 18-inch drive, or to practical refusal, were converted to approximate SPT N-values[1] using 0.8 as the conversion factor to account for the larger sampler diameter and the automatic trip hammer.

3.6.2 Hand Auger Borings

Gregg Drilling and MACTEC staff advanced hand auger borings in locations that were inaccessible by motorized equipment or where depth of penetration was minimal. Five hand auger borings were advanced using a 3-inch diameter "spoon auger" with rod extensions, at locations shown on Figure 2. These borings ranged in depth from one to 13.2 feet. Discrete samples were obtained for analysis and logging.

3.6.3 Direct Push Borings

Precision Drilling advanced three direct push borings at locations in the GGBHTD parking area as part of the additional area investigation west of Merchant Road. MACTEC's field geologist logged and collected continuous core samples to depths ranging from 7 to 10 feet (ft) bgs. Discrete samples were retrieved for analytical testing.

3.6.4 Boring Abandonment

Most of the borings were abandoned by backfilling with borehole cuttings. However, hollow stem borings drilled in higher traffic areas on the bluff top and the GGBHTD yard (BBSB100, BBSB101, BBSB103, BBSB106, BBSB117, BBSB118, and BBSB119) were backfilled with bentonite cement grout or bentonite chips. The backfill method for these borings deviated from the draft sampling plan due to field conditions. Because the borings in the GGBHTD yard were in asphalt and in a high traffic area, it was necessary to use a mix of cement-bentonite grout to allow for quicker set up of the hole and to prevent future settlement of the borehole. The remaining borings that were backfilled with bentonite chips were done so due to logistical constraints (limited access) with mobilizing the bentonite mixer.

3.6.5 Piezometer Installation, Development, Monitoring, Sampling, and Seep Sampling

AIS installed two piezometers at BBDA-1 at the top of the seep (BB1PZ100) and near the midpoint of the seep zone (BB1PZ101) using hollow stem augers mounted on the Spyder excavator. Piezometer BB1PZ100 was screened in bedrock (12 to 15.2 ft bgs) and BB1PZ101 was screened in waste fill (4.2 to 9.2 ft bgs). Appendix A3 contains piezometer completion details. After their installation, the two

[1] The SPT N-value is defined as the number of blows of a 140-pound hammer, falling freely through the height of 30 inches, required to drive a standard split-barrel sampler (2-inch outside diameter and $1\frac{3}{8}$-inch inside diameter) the last 12 inches of an 18-inch drive. For SPT procedures, see ASTM D1586-84.

piezometers were developed by swabbing and bailing using 2-inch diameter PVC bailers. Approximately 3 to 11 well volumes were removed during development from BB1PZ100 and BB1PZ101, respectively. Water levels were measured in May, August, September, October 2005, and February 2006 using an electric water level indicator in accordance with Trust protocols (Trust SOP). Copies of field notes summarizing the water levels and calibration protocols are included in Appendix A3.

MACTEC collected three rounds of groundwater samples from BB1PZ101 and one from BB1PZ100. The first round of samples was collected from BB1PZ101 on May 27, 2005, using a dedicated bailer. The piezometer was purged of approximately four well volumes prior to sample collection. Samples collected from the piezometer were submitted for analytical testing for volatile organic compounds (VOCs), polycyclic aromatic hydrocarbons (PAHs), dioxins and furans, total petroleum hydrocarbons (TPH) as gasoline, diesel and motor/fuel oil, pesticides, polychlorinated biphenyls (PCBs), and dissolved metals. A trip blank was also collected and analyzed for VOCs and TPH as gasoline. The sample collected for metals analysis was field-filtered.

On August 1, 2005, a second sample was collected from BB1PZ101 after purging 4.3 well volumes. During this round of sampling, one field-filtered sample was collected and analyzed for dissolved Title 22 metals, and one sample was collected that was not filtered and was analyzed for total Title 22 metals. On February 1, 2006, a third round of groundwater samples were collected from BB1PZ101 after purging 4 well volumes of water from the piezometer. The groundwater sample was analyzed for VOCs, PAHs, TPH as gasoline, diesel, and motor/fuel oil, pesticides, PCBs, dissolved metals (field filtered sample), total metals (unfiltered sample), and general minerals.

On February 1, 2006, a groundwater sample was also collected from BB1PZ100 after purging approximately 2 casing volumes of water. During this round of sampling, one primary sample and one duplicate sample were collected. A surface water sample (BB2ASW100) was collected from a newly identified seep located at the base of BBDA-2A. Samples were analyzed for VOCs, PAHs, TPH as gasoline, diesel, and motor/fuel oil, pesticides, PCBs, dissolved metals (field filtered sample), and dissolved metals (unfiltered sample), and general minerals.

3.6.6 Sampling Methodology and Sample Identification Scheme

3.6.6.1 Soil Sampling Methodology

The following describes methodology used to collect samples from soil borings and trenches.

Soil Borings - Soil samples were collected from borings using Shelby tubes, a SPT split barrel sampler, or California-modified split barrel (Cal-Mod) sampler. The SPT and Cal-Mod samplers were lined with stainless steel tubes (for chemical testing) or brass tubes (for geotechnical testing).

Test Pits and Trenches - Soil samples were collected from trenches and test pits by (1) pushing a clean stainless steel tube into the sidewall of the trench/test pit or (2) in cases where the trenches/test pits were deeper than 4 feet, by retrieving soil using a backhoe bucket and pushing a stainless steel tube into soil within the bucket.

Surface or Shallow Soil Samples - Surface or shallow soil samples were collected using a hand auger or shovel and stainless steel tube.

Soil samples tubes collected for chemical analysis were capped with Teflon-lined caps and placed in a cooler with ice for transport to the laboratory.

3.6.6.2 Groundwater/Surface Water Sampling Methodology

The following describes methodology used to collect groundwater and surface water samples from piezometers and seeps at BBDA-1 and -2A.

Piezometer Sampling - Prior to collection of groundwater samples, the piezometers were purged approximately three casing volumes or bailed until dry. The wells were purged using a dedicated polyethylene bailer that was stored inside the well. While purging, the pH, conductivity, temperature, and turbidity of the purged water were measured and recorded on sample collection forms. After purging, samples were collected from the piezometers using the dedicated polyethylene bailer and decanted into laboratory-supplied containers.

Seep Sampling - Water samples were collected from the seep at BBDA 2A by immersing sample containers in water running at the surface of the fill until the sample containers were filled.

Samples were placed in a cooler with ice for transport to the analytical laboratory.

3.6.6.3 Sample Identification Scheme

Protocols from the Presidio Quality Assurance Project Plan (QAPP) were generally followed for sample identification. For this report, to distinguish multiple groundwater samples collected from a given sampling station on multiple dates, the station identification (ID) was appended with the sample date. In addition, because both filtered and unfiltered samples were collected for metals analysis, the sample that was not filtered was appended with the letters "UF" to distinguish the results from those for the filtered sample. These samples are distinguished in the Trust's database by the "metal DIS" in the ANALGROUP field for the filtered sample while the ANALGROUP for the unfiltered sample is designated as "metals". In cases where samples were collected from the same depth from a test pit for both geotechnical testing and chemical analysis, the samples for geotechnical testing are shown in a different color on the test pit log to distinguish them from samples collected for chemical analysis.

3.7 Laboratory Testing

Laboratory testing was performed on representative soil, rock, and water samples from the borings, test pits, and trenches. Testing was done in accordance with the appropriate Geotechnical and Environmental FSPs (*MACTEC, 2005e and f*), and under general protocol requirements of the Presidio QAPP (*Tetra Tech, 2001*). Appendix C presents laboratory test results.

3.7.1 Geotechnical Testing

MACTEC re-examined the soil samples from the borings to check field classifications and to select appropriate samples for geotechnical laboratory testing. Selected geotechnical samples were submitted under chain of custody to RGH Geotechnical, Inc. Santa Rosa, California. Geotechnical tests performed included moisture content, dry density, Atterberg limits, particle size analysis (including hydrometer and -200 sieve); and shear strength using Triaxial consolidated-undrained and unconsolidated-undrained techniques, and direct shear methods Laboratory test results are shown on the boring logs in accordance with the key in Appendix A3. Additional strength plots, Atterberg Limit plots, and Sieve Analysis plot results are shown in Appendix C1.

3.7.2 Analytical Testing

MACTEC collected environmental samples from soil borings and cultural resources trenches. In addition, analytical samples were collected from some of the deeper test pits to characterize deep soils, and water samples were collected from onsite piezometers for analysis. One sample was also collected from incinerator waste material that appeared to contain ash.

Samples were collected in stainless steel tubes and Encore™ samplers, and were transported under Chain of Custody to Curtis Tompkins Laboratory, Berkeley, California. Soil samples were analyzed for:

- Polyaromatic Hydrocarbons (PAHs; test method SW 8270SIM)
- California Code of Regulations (CCR) Title 22 metals (Test Method SW6010/6020-7000 series)
- Organic Pesticides (Test Method SW8081A)
- Polychlorinated Biphenyls (PCBs; Test Method SW8082)
- Total Petroleum Hydrocarbons (TPH; Test Method 8015m). Soil samples were analyzed for TPH quantified as diesel (C12-C24) and TPH quantified as fuel oil (C24-C36). Because the same carbon range is used for fuel oil and motor oil, the text refers to results in terms of TPH motor oil/fuel oil.
- Volatile Organic Compounds (VOCs; SW 82608)
- Moisture Content (American Society for Testing and Materials [ASTM Test Method D-2216]).

The sample collected from incinerator waste containing ash was analyzed for analytes listed above plus dioxins and furans using Test Method 8290. Water samples were analyzed for VOCs and Title 22 metals, and general water quality (major cations and anions); total non-filtered (SW 6010/6020-7000 series), and dissolved metals, field filtered (SW6010/6020-7000 series). Appendix C2 summarizes the laboratory analytical results for soil and water samples; and Appendix C3 presents data validation results. Results of the data validation indicate that the data are usable with the exception of the nondetect result for antimony for sample BB2SB110(0.5) which was qualified as rejected because the percent recoveries were less than 30 percent.

3.8 Baseline Structural Evaluation and Inspection of Batteries

The purpose of structural evaluation was to:

- Provide a baseline condition survey of the fortifications (Battery Godfrey, Battery Boutelle, Battery Marcus Miller, and brick magazines 21, 22, 27, 28, and 29) before landfill removal and as a basis for monitoring during construction;
- Assess the cause of existing cracks in Battery Boutelle (e.g., are they present as a result of slope instability); and
- Assess whether it would be possible to transport waste from BBDA-1A over the top of Battery Marcus Miller; and recommend mitigation measures during construction, if required.

This study did not assess the historic significance of any element of the fortifications. SOHA performed the structural evaluation in Spring 2005. Structural engineers and technicians inspected the interior and

exterior conditions of the batteries, and photographed selected elements of each fortification to identify hazardous or potentially hazardous conditions.

SOHA's report is presented in Appendix F, and includes their findings regarding the baseline condition and structural integrity of each battery. SOHA evaluated the source of cracks apparent at Battery Boutelle as part of this baseline condition assessment. The Trust plans to contract SOHA to perform additional evaluation and reporting prior to and during remediation.

3.9 Water-side Waste Removal Assessment

As part of the pre-design studies, MACTEC met with several potential contractors to assess the possibility of water-side removal of waste as an alternative to removal of the waste from the bluff top.

An approach to a water-side removal was discussed with two contractors familiar with marine salvage and dredging operations. A bathymetric survey was conducted north of BBDA-1 to investigate bringing a barge onto the beach and transporting debris offside via the beach. This approach was not deemed feasible because of offshore obstructions and limitations presented by the tide and beach steepness.

4.0 REGIONAL GEOLOGY

To understand geologic and geotechnical conditions in the Baker Beach area, it is important to understand the regional geology, natural geologic processes, and the debris placed along steep slopes (some of which contain natural seeps).

This section on regional geology provides a description of the geologic setting of the California borderland and the San Francisco Peninsula, a review of regional faulting and seismicity, and a summary of hydrogeologic conditions of the Presidio. These broad factors then form a basis for more detailed discussions of geologic hazards, presented in Section 5.0, and site-specific geologic units for each of the BBDAs discussed in Section 6.0.

4.1 Geologic Setting

The Presidio is located within the California Coastal Range Province, which is characterized by northwest-trending ridges, broad basins, and valleys, generally paralleling major geologic structures (*Shlocker, 1974*). Throughout most of this region, basement rocks lie at shallow depths and are composed of highly consolidated and tectonically deformed sedimentary, volcanic, and metamorphic rocks of the Franciscan complex. The regional geology of the area is shown on Figure 3B.

The Presidio is underlain by unconsolidated deposits consisting of the Colma Formation, dune sands, slope debris and ravine fill, beach deposits, and artificial fill (Figure 2). These unconsolidated deposits overlie late Jurassic to late Cretaceous-age Franciscan assemblage rocks. In the San Francisco Area, the Franciscan complex consists of greywacke sandstone, shale, siltstone, chert, and mafic volcanic rocks (basalt and diabase), and metamorphic rocks, including serpentinite (*Shlocker, 1974* in *Tetra Tech, 2001*).

The Pleistocene-age estuarine and marine Colma Formation is present in the southern and southeastern part of the Presidio, where the formation rests unconformably on Franciscan complex rocks. The Colma Formation consists of unconsolidated fine to medium-grained sand with moderate amounts of silt and clay. Within the Presidio, the thickness of the Colma Formation ranges from 75 feet to as much as 300 feet (*ANL, 1989* in *Tetra Tech, 2001*).

Dune sand, consisting of fine to medium-grained sand, forms surficial deposits in the southwestern and central portion of the Presidio. This unit is typically less than 100 ft thick, but reaches thickness of up to 150 ft in the southwestern corner of the Presidio (*TetraTech, 2001*).

Slope debris and ravine fill, consisting of sand silt and clay, form surficial deposits in upland areas north and east of the dune sand. The maximum thickness of this unit is estimated as 150 ft (*ANL, 1989* in *Tetra Tech, 2001*).

Beach deposits and artificial fill comprise surficial deposits along San Francisco Bay and along the Pacific Ocean at Baker Beach. The beach deposits consist of well-sorted, medium to coarse-grained sand, with minor gravel. Sands are interbedded with silts and clays comprising Bay Mud along the San Francisco Bay margin (*Tetra Tech, 2001*). Artificial fills also include those placed at landfill sites and engineered fill for roadways and buildings.

4.2 Faulting and Seismicity

The Presidio lies in a seismically active area between the San Andreas and Hayward/Rogers Creek fault systems. The San Andreas Fault System is located about 7 miles west of the center of the Presidio. The Presidio overlies the northwest trending Fort Point-Potrero Hill shear zone. This shear zone is considered

inactive because it does not dissect rocks that are younger than Cretaceous (*E.C. Jordan Company, 1990* in *Tetra Tech, 2001*).

Figure 3B shows significant active faults [2] in the region. Table 2 lists the distance from these faults to the site along with the maximum moment magnitudes for each fault based on fault length and historical seismic activity.

Numerous earthquakes have occurred in the San Francisco area, occasionally resulting in damage to structures. Most of these earthquakes have been attributed to either the San Andreas Fault to the west or the Hayward Fault to the east. Historical accounts of the San Francisco Bay Area note numerous damaging earthquakes since the early 1800s (*Tooker, 1959*). The great California earthquake occurred on April 18, 1906. As shown on Figure 3B, its epicenter was offshore, on the San Andreas Fault. The historic record of damage to the Baker Beach area is not complete. Ground failures in the immediate project vicinity were not noted following the 1906 earthquake (*Youd and House, 1978*). Other damaging earthquakes on the San Andreas Fault occurred in 1838 and 1865. In 1838, surface breakage extended from San Francisco to Santa Clara, and serious damage occurred to Mission Dolores and to the Presidio. The 1865 event was centered in the mountains near Santa Cruz, but caused damage in San Francisco to structures on filled ground. Earthquakes that occurred on the Hayward Fault in 1836 and 1868 also caused damage in San Francisco. The 1868 event caused considerable damage to buildings on filled ground (*Lawson, 1908*). A fissure was noted in the bank near Fort Point (*Youd and House, 1978*). An estimated Magnitude 7 earthquake on the Calaveras Fault was reported in 1861. The epicenter of the Loma Prieta earthquake, which occurred in October 1989, was located 96 kilometers (km; 60 miles) to the south of San Francisco in the Santa Cruz mountains. It caused damage in certain areas of San Francisco that are underlain by soft or otherwise unstable soils, but caused little damage to the area of the subject sites for this report.

4.3 Regional Groundwater Hydrogeology

Groundwater at the Presidio occurs in both unconsolidated and bedrock aquifers. Water-bearing units include the following:

- Beach sand deposits adjacent to Baker Beach and San Francisco Bay;
- Dune sands and the Colma Formation in the southwestern and central portions of the Presidio;
- Fill deposits; and
- The Franciscan Assemblage Bedrock, which underlies unconsolidated deposits. The water table occurs in fractured or sheared bedrock in upland areas where unconsolidated deposits are not saturated.

Groundwater recharge primarily occurs due to infiltration from irrigated areas and from precipitation. Groundwater discharge occurs as seepage to Mountain Lake and Lobos Creek, spring discharge at El Polin Spring and other springs at the Presidio, possibly the Palace of Fine Arts Lagoon, and seepage to San Francisco Bay and the Pacific Ocean (*Tetra Tech, 2001*). The permeable sands of the Colma Formation act as an aquifer, and springs are common at the interface of the Colma Formation and the underlying serpentinite (*Elder, 2001*).

[2] "Active faults" are defined as those exhibiting either surface ruptures, seismic activity, topographic features indicative of faulting, surface displacements of geologically recent or Holocene deposits (geologic deposits that are younger than 10,000 years old), tectonic creep along fault lines, and/or close proximity to linear concentrations or trends of earthquake epicenters.

The water table surface tends to follow topography where groundwater generally moves from upland areas towards San Francisco Bay and the Pacific Ocean. However, buried bedrock surfaces could locally control the direction of groundwater flow.

Three groundwater basins, the Lobos Creek Groundwater Basin, the Coastal Groundwater Basin, and the Marina Groundwater Basin, have been identified at the Presidio as shown on Figure 4B. Baker Beach is within the Coastal Groundwater Basin, based primarily on its position relative to the drainage divide east of Lincoln Boulevard and all areas that drain towards the Pacific Ocean.

Seeps have been identified along the coastal bluffs, both at Baker Beach 3, and at BBDA-1 and -2A. Perched water table conditions may exist at BBDA-2 during the wet season. These seeps are probably the result of groundwater flow through bedrock fracture zones based on observations at the Baker Beach 3, area and other Presidio coastal areas. Based on field observations to date, it appears that the seep at BBDA-1 may be perennial. It is not known if the seep at BBDA-2A seasonal or perennial. The seep at BBDA-2A was first discovered during the Spring of 2005 and also observed and sampled in February 2006. It is not known if the seep was flowing during the drier Summer months. It is planned to be monitored quarterly as part of the basewide groundwater monitoring program.

5.0 POTENTIAL GEOLOGIC HAZARDS

Due to the steepness of the topography of the project area and its location within an area of high seismicity, the principal geologic hazards for the project consist of the potential for strong groundshaking and landslides induced by earthquakes occurring along one or more of the regional active faults. Other geologic hazards considered for this investigation include earthquake-induced liquefaction, settlement and lateral spreading, expansive soils, tsunamis and fault rupture. A discussion of each geologic hazard follows.

5.1 Seismic Groundshaking

The intensity of groundshaking, in response to earthquakes on one or more of the regional faults, is a function of distance to the causative fault, the magnitude and duration of the earthquake, and the nature of the underlying soil and bedrock. The two closest, significant faults to the project are the San Andreas Fault, and the Hayward-Rodgers Creek Fault, as previously noted in Table 2 and shown on Figure 3B. The San Andreas Fault is capable of a 7.9 moment magnitude (Mw) event with an estimated bedrock acceleration of 0.55g. The Hayward-Rodgers Creek fault is capable of a 7.0 Mw and 0.20g respectively (*WG02, 2003*). Shaking intensity, as measured by the Modified Mercalli Intensity Scale (Table 3) has been estimated at IX for a modeled earthquake similar to the 1906 event on the San Andreas fault, and a VII for a combined event on the Northern Hayward and Rodgers Creek fault (*ABAG, 2003*).

The California Building Code requires estimation of peak horizontal accelerations for the upper bound earthquake (UBE). The UBE ground motion is defined as the motion having a 10 percent probability of being exceeded in a 50-year period or the maximum level of motion that could ever be expected at a site based on the known geologic framework. Based on this definition, a 7.9 Mw earthquake on the nearby San Andreas Fault is considered the UBE. For an earthquake of this magnitude, peak horizontal accelerations in bedrock at the project site would be expected to be approximately 0.55g (*CDMG, 2001*). A large earthquake on the Hayward and/or Rodgers Creek faults would be a more frequent occurrence, but the measured ground motions at the site would be less than the San Andreas Fault.

5.2 Liquefaction and Lateral Spreading

Liquefaction is the phenomenon in which loose, saturated, granular materials experience a sudden loss of shear strength due to seismic shaking. Soil liquefaction can induce sand boils, differential settlement, lateral spread, and ground failure. The California Geological Survey (CGS) has not included the project area with their liquefaction seismic hazard maps (*CDMG, 2001*). Elsewhere in San Francisco (e.g., the Marina District) liquefaction occurred as a result of the Loma Prieta earthquake, causing localized settlement and sand boils emanating from loose, saturated sand fill.

Liquefaction would be expected to occur at the project site under conditions where seeps are observable within waste fill areas, fill slopes are partially saturated, and the fill materials are loose. During excavation of test pit BB1TP106, a zone of saturated waste fill was mobilized as a slow moving debris flow downslope along the seepage swale towards the beach by either vibration from the Spyder excavator or by saturated, unsupported fill slope in the side of the excavation. It is possible that loose, saturated sandy fill is present at the base of BBDA-1 and 2A that could liquefy during similar construction operations.

Bluff top fill areas and areas underlain by shallow bedrock are not susceptible to liquefaction or settlement, and associated differential settlement and lateral spread within the area of existing batteries and other structures is considered very low.

Lateral spreading is caused by movement of steep, unsupported slopes toward the free face can be a secondary effect of liquefaction. Although the lower beach cliffs (below elevation 25 feet Presidio lower low water [PLLW]) are relatively steep, these bluffs are composed primarily of Franciscan mélange, or sandstone and shale bedrock, and therefore not considered susceptible to liquefaction and lateral spreading.

5.3 Tsunamis, Seiches, and Flooding

Given the high topography of the project area, flooding from tsunamis is unlikely except for the beach areas at the base of the lower beach cliffs. Inundations from tsunamis, seiches, or flooding are generally observed in low-lying, flat terrain. Tsunamis are typically caused when a large water body is displaced by normal or reverse fault movement. Most movement on the San Andreas Fault consists of a lateral (dextral) slip component, which would not include a large displacement of water to create a tsunami. However, a tsunami from a more distant source is possible. Following the 1964 Alaska Earthquake, a tsunami traveled southward to central California, and entered San Francisco Bay. Although wave amplitudes were measured at height of 1 meter at the Golden Gate, no measurements are known to have been taken at Baker Beach. Due to the height of the Presidio coastal bluffs, even with a 5-meter wave height the lower portions of BBDA-1 and -2A would not be flooded.

The relatively high elevation of the project site suggests that flooding is not a concern. Neither is the site adjacent to an enclosed or semi-enclosed body of water (i.e., San Francisco Bay) that might be vulnerable to enlarged wave runup caused by a seiche (sloshing of enclosed water due to earthquake shaking).

5.4 Fault Rupture Hazard

No known active faults cross through the project site (*Hart, 1999*). Fault ground rupture is normally associated with zones of active faulting and/or planes of weakness adjacent to active fault zones. The closest active fault is the offshore section of the San Andreas Fault, located 12.1 km (7.6 miles) to the west. Because recognized active faults neither cross through, nor are adjacent to the site, the fault rupture hazard at the site is considered to be negligible.

5.5 Landslides and Slope Instability

In general, landslides pose a hazard to cliff top structures and people located on or below steep slopes at Baker Beach. Pervasively weak bedrock materials, steep slopes, exposure to rainfall, and undercutting by wave action have all contributed to the inherent instability of slope materials. Less common causes of landslide in the area are adverse bedding, localized discharge of surface runoff, and dumping of waste fill. Since the 1960s, the growth of vegetation appears to have provided some stabilization of the fill slopes.

During geologic reconnaissance, MACTEC mapped active landslides along the slope face (Figure 2). MACTEC mapped debris on the beach during the beach survey, presumably from waste fill areas above. It would be expected that natural processes would periodically move rock and saturated soil from the bluff top and slope face onto the beach. MACTEC observed some translational sliding along adverse bedding of shale units. Earthflow-type landslides (Qls) were observed north and south of BBDA-1 and BBDA-2A. Farther up the slope just below the bluff-top cliffs, larger, slumping was observed, partially obscured and coalescing with debris and waste fill. The hard, more competent serpentinite cliffs occasionally shed variable size rock fragments due to jointing in the intact rock. These landslides are indicative of the overall slope instability in the area. The risks of additional movement of materials down the slope are greatest during winter rains and during earthquakes.

6.0 SITE CONDITIONS

This section presents a summary of site conditions with respect to the site geology and hydrogeology, the cultural landscape, the structural competence of existing historical batteries, and the nature and extent of contaminants in soil and groundwater at the site. An understanding of the nature and extent of contamination in and around the disturbed areas, the vertical and lateral extent of geologic units and their geotechnical properties, the location, nature and stability of cultural resources is important input to remedial design plans. Development of remedial options requires understanding of the nature and extent of contamination, slope stability, and the location, type, and integrity of nearby cultural resources.

The following sections describe general site conditions for the BBDAs, including surface and subsurface geology. The discussion is based on a comprehensive review of data collected previously and during the current investigation. The purpose of this section is to synthesize these data to formulate a conceptual model for site conditions at each of the BBDAs.

6.1 General Site Conditions

The following provides a description of the overall BBDA Area. Site conditions for each of the BBDAs are described in Sections 6.2.1 through 6.2.5.

6.1.1 Surface Conditions

Surface conditions at the BBDA site are characterized by sparse to thick vegetation, hummocky topography with coalescing deposits of soil and waste fill perched on slopes that range from near vertical to flat (Figure 2). In general, the steepest portions of the bluffs are found along landslide scarps and serpentinite cliffs. Elevations range from near sea level to 274 feet PLLW. Each of the four BBDAs and surrounding areas are discussed below.

6.1.2 General Lithologic Descriptions

Soil and Bedrock Units

The following sections provide generalized descriptions of the geologic units present at the site that correspond to the geologic units shown in plan view on the geologic map, Figure 2, and in the maps and cross-sections on Figures 5 through 8. More detailed site-specific descriptions follow by BBDA in Section 6.2.

Artificial Fill

Artificial fill covers much of the site and includes historical fill as well as waste fill. Historical fill is classified as human-placed fill that can contain minor amounts of waste material that was placed in conjunction with the historical batteries. In general, this fill consists of wood planks and bricks associated with demolition of the earlier fortifications. Historical fill has been divided into the following sub units:

- **afh** – Historic fill associated with the most recent construction of the batteries, which incorporated some buried sections of the Battery West era earthworks and are generally contiguous with the concrete structures. It is a culturally significant resource that generally does not contain contaminants above cleanup levels and will be protected during remediation.

- **afh1** – Historic fill associated with the removal of the previous battery structures. Much of this fill has been displaced during construction of the Endicott Batteries, and is significant as a cultural resource that generally does not contain contaminants above cleanup levels. It is anticipated that this material will be protected during remediation.

- **afh2** – Historic fill associated with the removal of the previous battery structures that has been disturbed and displaced downslope. Depending on the location the displaced fill relative to waste fill, the fill associated with waste fill may contain contaminants above cleanup levels and may be removed during remediation of the waste fill.

Waste Fill (**afw**) is human-placed waste debris associated with construction demolition, household waste, and vegetative (organic) waste. It is planned that this material be removed during the remedial action.

Other Fill (**afo**) is human-placed fill of uncertain origin, generally found outside the historic boundaries of the barbettes or more recent Endicott Period Batteries, and contains engineered and non-engineered fill. It is not anticipated that this fill will be removed during the remedial action. Where this fill contains construction debris it has been mapped as **afo1**.

Quaternary Deposits

Landslide deposits (**Qls**) occur throughout the study area, but are not broadly present at the ground surface in the debris areas. In some locations, artificial fill overlies and conceals landslide deposits and colluvium. The landslide deposits are considered to be of Quaternary Age.

Native Soils (**Qcol**) represent in-place soils and unconsolidated sediments of various origin, but are collectively mapped due to their similar geotechnical characteristics. These include Quaternary-age Colma formation soils, as well as colluvium and residual soils that represent residual weathered bedrock. In general, these materials consist of clays, sandy clays, and clayey sands, with varying amounts of gravels and occasional cobbles and boulders.

Beach Deposits

Beach Deposits (**Qb**) are found exclusively in the tidal zone at the base of the project area. They contain variable amounts of debris that are partially buried, as well as driftwood and trash. The beach deposits are very poorly consolidated and comprise poorly sorted sand, sand and gravel, and locally also include boulders. Deposition patterns and beach sand levels are directly related to wave and tidal action.

Bedrock

Mélange (**KJm**) occurs predominately on the lower portions of the slopes, and consists of shale, mudstone, and varying large blocks of sandstone and siltstone in a sheared matrix. Mélange materials are inherently unstable, and rest in shear contact with serpentinite.

Sandstone (**KJss**) and Shale (**KJsh**) are found as large, coherent blocks of greywacke sandstone and siliceous, thinly bedded shale. The blocks can be contained with the larger mélange unit, and are generally harder and stronger than the surrounding matrices. The sandstone and shale are usually bounded by shear zones, and are located on the lowermost project slopes.

Serpentinite (**sp**) is an ultramafic rock that dominates the upper portion of the slopes, ranging locally in slopes as steep as vertical or even slightly overhanging. The rock is massive, with random shear surfaces and joints, and weathers to a yellow brown silty or sandy clay. Large landslide scarps in serpentinite occur south and north of the debris areas.

Groundwater

Based upon hydrogeologic information from the Remedial Investigation (*Dames & Moore, 1997*) and MACTEC's field observations from lithologic logging and monitoring water levels in two piezometers installed for this investigation, groundwater occurs as a perched zone within landslide deposits or waste fill, or as bedrock seeps within weathered serpentinite bedrock. Two freshwater seeps originate approximately mid-slope of BBDA-1 (located within the seep zone shown on Figure 5). A seep was also observed in the lower portion of BBDA-2A (Figure 8). These seeps are thought to be the result of groundwater flow through bedrock fracture zones, similar to what has been observed elsewhere on coastal bluffs within the Presidio. As discussed in Section 3.6.5, two piezometers at the seep at BBDA-1 and the seep at BBDA-2A were sampled in May and August 2005 and in February 2006.

6.1.3 Cultural Resources Investigation

A CRI was performed by URS (Appendix B) to provide a description of the physical and historical setting and a comprehensive assessment of cultural resources located in the BBDA area. The assessment included historical research and a field investigation. The field investigation included exploratory trenches along the bluff top in the vicinity of the former West Battery; as well as visual surveys of existing West Battery fortifications.

A comprehensive historical narrative (*URS, 2005;* Appendix B) of the West Battery and Fort Scott Endicott Batteries was prepared to provide information in support of the Cultural Resource Evaluation and is included in the CRI report. The historical narrative details the construction, evolution, and modification of the fortifications. It describes the U.S. Army Corps of Engineers design and construction of the "works," as the fortifications were then called, and provides a historical timeline as well as a description of alterations to the slopes and structures. Of particular relevance to the remedial efforts at Baker Beach are historical records (maps and photos) of incinerators, which were present in the area from 1922 and 1934, as well as historical disposal and fill activities that occurred in areas adjacent to the Batteries in the middle of the twentieth century.

The results of the CRI, which describes the type of soils and their stratigraphic relationship, correlate well with mapped geology and the environmental investigation and provide important information as to how waste fill and historic fill were deposited. The historic sequence of events includes:

- Construction of the West Batteries between 1870 and 1876, which included construction of magazines and the covered way.
- Construction of the Endicott Period Batteries between 1891 and 1901.
- Disposal of waste fill began at an undetermined date probably sometime around World War I.
- Construction of two waste incinerators in 1922 and 1934 and overall dumping continuing until around 1967, with some possible fill placement associated with construction of the Golden Gate Bridge (1936 to 1937).
- Construction of the parking area on the south and west side of Battery Godfrey possible occurred after 1954 when access roads were built leading to the dump and recycling areas to the south.

Some significant findings from the report that are pertinent to an understanding of site conditions and development of remedial design strategies include:

- The West Battery fortifications required the use of granite blocks, masonry for gun platforms and magazines, and sod for slopes. The fortifications extended for a length of 1,324 feet and upon being finished required 29,586 cubic yards of imported soil of which 7,180 cubic yards was sod (22,406 cubic yards of soil that is not sod). This volume of soil is documented as being used for the West Battery Fortifications and thus provides an upper bound to the quantity of historic fill (afh1) potentially present downslope of the batteries that was displaced when Endicott Batteries were constructed.

- By 1901, five different Endicott Batteries had been built atop the West Battery fortifications. Battery Boutelle, the last Endicott Battery built (between 1898 and 1901) was nestled between the existing West Battery earthworks associated with Magazines 22 and 23.

  These new works covered or displaced nearly every trace of the 1870s emplacements. The most recent historic fill (afh) abuts against the Endicott Batteries and was essentially placed as backfill against the concrete walls comprising the batteries. Older historic fill (afh1) may be fill derived from the West Batteries that was likely removed and spread out to make room for the newer batteries. The adjacent grades corresponding with traverses and superior crests for the new Endicott Batteries were lower than the previous crest of the West Battery, implying that earthworks associated with the former West Battery were relocated. In fact, it appears from geologic mapping that this displaced historic fill (afh1) was pushed downslope and spread behind Batteries Godfrey and Marcus Miller.

  Waste fill in BBDA-2 was placed on a cut surface that removed some vestiges of West Battery earthworks and Endicott Period cultural resources, although substantial portions of the frontal slope remain buried in that area, presumably to create the parking lot located adjacent to Battery Godfrey. The presence of the cut surface in this area indicates that historic fill (afh2) downslope of the parking lot in BBDA-2A may have been pushed over the bluff top during on-going modifications subsequent to the West Battery era.

- There were several episodes of dumping at BBDA-1. Waste disposal activities began with direct downslope dumping of debris and refuse generated possibly from the barracks to the east. Later waste dumping that may have been contemporaneous to or after incineration was noted. The dump area reached its maximum lateral extent in 1967.

- Other significant filling events along the bluff top included:

  - The raising of the Covered Way by 8 feet adjacent to the entrance of Magazine 27;

  - The placement of between 12 to 15 feet of fill from battery demolition or Golden Gate Bridge earthwork sources on the rear slopes of the Covered Way; and

  - Fill piles noted in a 1967 photo near the GGBHTD offices that may have been generated from construction of the Presidio Letterman Hospital.

- The remnants of four mortar platforms and the adjacent opening to Magazine 21 were exposed in Trenches 4 and 5 during excavation and logging activities of the CRI. These platforms were identified as being of historic significance and represent the depth at which historic earthworks and the former Covered Way road surface would be encountered.

- Although waste fill was not observed in direct contact with the structural concrete or brick remains of fortifications in exploratory trenches logged as part of the CRI, it is quite likely that waste fill is in contact with undisturbed historic fill at BBDA-1 and -1A.

- A pervasive marker bed of chert fill was observed in cultural resource trenches at BBDA-1 and BBDA-2. Although it is unclear exactly what this layer represents, it is believed to be the surface of an access road and it may provide a marker for identifying the base of the waste fill during removal.

It is important to note that the historic fill on the bluff top generally does not contain contaminants above cleanup levels and, whether undisturbed or displaced, is considered an historic resource that needs protection during remediation, unlike the historic fill cast down the slope that may contain contaminants above cleanup levels and does not require protection. Excavations to remove waste fill may expose adjacent historic fill. The design should incorporate methods and requirements for protection of this resource, where appropriate.

6.1.4 Geophysical Mapping

In 2003, a geophysical field investigation was performed to further assess of the extent of refuse at BBDA-1, BBDA-1A, BBDA-2, and BBDA-2A. The geophysical field investigation included an electromagnetic (EM) terrain conductivity survey and a GPS survey. The EM31-D instrument consisted of transmitter and receiver coils mounted on each end of a 10-foot long PVC boom. Terrain conductivity data were collected by hand-carrying the EM survey system along survey transects covering an approximately 1,600 X 300 foot area. EM data were collected at 0.5-second intervals, which corresponded to an EM measurement for approximately every 2 feet of surveyed transect. An estimated 31,600 line-feet or nearly 6 miles were surveyed during the field investigation. GPS mapping of the exposed refuse was performed with a Trimble Pro-XRS GPS. The GPS was also used to provide positioning data for the EM survey.

In order to illustrate and quantify the data collected from the EM and GPS surveys, several computer programs were used. DAT31W, OASIS Montaj, and Trimble Pathfinder Office software were used to combine EM and GPS data into single files suitable for computer contouring and mapping. A color-filled terrain conductivity map and refuse location map were produced and then combined to facilitate assessment of refuse extents in the four disturbed areas; these Figures are presented in Appendix G. Figures 4 through 8 also show the extent of refuse as interpreted from the geophysical mapping. Results of the survey are presented and discussed in Appendix G.

6.1.5 Battery Structural Evaluation

A Baseline Structural Inspection (Appendix F) was conducted by SOHA Engineers (*SOHA, 2005*) to assess the current condition of the fortifications, and to anticipate potential problems that could arise during and after remedial activities. A narrative discussion of the construction and general condition of the fortifications is included, as are photographs, schematic plans, and a summary of potentially hazardous items. The assessment also provides a discussion regarding the cracks observed in Battery Boutelle, and of possible construction loading at Gun Pit #1 at Battery Marcus Miller.

Results from this report include:

- The general condition of Batteries Godfrey and Marcus Miller indicate wear commensurate with long-term exposure to harsh elements. However, no overall instability was observed.

- Battery Boutelle exhibits a wear pattern similar to that observed at Batteries Godfrey and Miller. However, large cracks, up to 3 inches in width, were noted around the parapet wall. This condition was not observed in the magazine rooms. An evaluation was performed by structural specialists to determine the cause of the cracking. It appears that the battery aprons were placed after the completion of the battery structure, and the area beneath the aprons contains fill of substantial depth.

Possible causes of cracking include settlement of backfill under the battery apron, or movement of the soil mass west of the parapet wall toward the coastal bluff. The report concludes that the proposed remediation and construction activities should not adversely affect the structural integrity of the fortifications, which are built on thick concrete foundations excavated up to 18 feet deep in the case of Battery Boutelle.

- Minor cracking and water intrusion was noted in Magazines 22, 27, 28, and 29. More extensive cracks were noted in Magazine 21 on the north wall, and extending to the east wall.

- Mitigation measures, including surveying, monitoring, crack gauges, and splinter-proofing are recommended prior to remediation. If needed, specific shoring measures are proposed for the roof of Battery Marcus Miller.

6.2 Area-Specific Site Conditions

This section presents a description of site conditions at each of the BBDAs.

Applicable Cleanup Levels

BBDAs 1, 1A, 2, and 2A are located in the Coastal Bluffs Planning Area within Area A of the Presidio, and therefore, are subject to land uses identified in the GMPA (*NPS, 1994*). Current and planned land use at BBDAs 1, 1A, 2, and 2A is recreational, with special-status ecological species potentially present on the slopes extending toward the beach.

Proposed applicable cleanup levels at BBDAs 1, 1A, 2, and 2A are based on the following criteria:

- **Protection of Human Health, Residential Use** – Although planned land use at the BBDAs 1, 1A, 2, and 2A is recreational, more stringent residential cleanup levels are used to eliminate the need for land use controls.

- **Bluff Slope - Protection of Ecological Receptors, Special-Status –** The portion of the site that lies along the bluff slope consists of an open space natural area. Both rare and federally-listed species are known or have potential to occur in this area. Accordingly, cleanup levels protective of special status species are considered applicable to this portion of the site. Figure 4A shows the areas where special status cleanup levels apply.

  Bluff Top/Merchant Road Area – Protection of Ecological Receptors, Ecological Buffer Zone – The portion of the site where there are parking areas, batteries, roads, and GGBHTD buildings are located in ecological buffer zone areas because that portion of the site is not planned to be restored to native plant habitat. Accordingly, along the bluff top and between the Covered Way and Merchant Road, ecological buffer zone cleanup levels apply (Figure 4A).

  Metals Background Concentrations for Serpentinite Soils – Lithologic units present in the area of the BBDAs primarily consist of waste fill, other fill, and historic fill that overlies native soils consisting of colluvium and residual soil on top of serpentinite. Colma formation soil may also overlie the serpentinite soil in certain areas of the site. Because the soil units were not easily distinguished in the field, they were mapped and logged as "Colma formation/native soils." Because of the predominance of serpentinite in the area and because bivariate scatter plots of concentrations of major elements in site soil samples performed as part of the Main Installation Sites FS confirmed a distribution of concentrations expected for serpentinite soils (*EKI, 2003*), background levels for serpentinite soil are used to evaluate metals concentrations at the site. For the Merchant Road Area,

where lithologic logs showed Colma overlying residual serpentinite soils, a combination of background levels for Colma and serpentinite soils were used to evaluate metal concentrations.

- **Protection of Groundwater at Drinking Water Levels** - For petroleum-related constituents, a depth to groundwater of greater than 5 ft was assumed in order to evaluate the leaching potential from soil to groundwater.

- The most stringent applicable cleanup level was selected as the cleanup level for each chemical or in the case of metals, the background metal concentration for serpentinite soil was selected as the cleanup level if it was greater than the other most stringent cleanup level for protection of human health or ecological receptors.

6.2.1 Baker Beach Disturbed Area-1

Surface Conditions

BBDA-1 is situated approximately at the center of the project area in a gap between Batteries Boutelle and Marcus Miller on the bluff top and is the largest debris area. It has a general concave topographic expression from debris stored on top of the bluff and deposited over the bluff downslope. Elevations range from 25 to 220 feet PLLW, with a significant vertical bedrock escarpment located directly below Battery Boutelle. The ground slopes are inclined at approximately 41 degrees at the top, 23 degrees midslope, and becoming more gentle (10 degrees) near the base. Debris which appeared to have fallen from the bluff top was mapped below a 25-foot high bluff above the beach. Debris is also buried in the beach sand, as discussed in Appendix H.

Vegetation has grown across the BBDA-1 area, and includes mature trees, tall shrubs, vines, bramble, and grasses. A perennial seep exists as a wetland midway down the waste fill slope, flowing to the beach (Figure 5). The spring supports water-dependent vegetative growth throughout the year. Much of the waste fill is super-saturated, as evidenced by depth to water measured in a piezometer installed within the waste fill down slope from the seep. Social trails cross the site, although the primary access trail to the beach skirts the northern edge of BBDA-1.

Artificial Fill

Fill at BBDA 1 generally consists of dark brown-grey clayey sand (sandy clay with concrete), with minor amounts of wood, metal, wire, slate, tile, plaster, brick, cobbles, asphalt, and glass (including bottles). In areas where the fill was substantially deeper, there was no obvious evidence of stratification of debris or soils. Although the fill consisted primarily of soils and construction materials, several test pits exhibited stratified debris where there was a higher incidence of household-type items (e.g., BB1TP103 and BB1TP102). Stratification of debris included household-type debris and metal trash mixed with burned material (Test Pit BB1TP106). Extensive areas of fill soil with limited construction debris were observed in trenches excavated in the central and south areas of BBDA-1. Stratified trash/incinerator layers were observed in trenches excavated in the northern portion of the site by the seep. The localized area of the incinerator and household debris indicates that the debris appeared to be consistently dumped from the same location on the cliff. Apparently, windblown lightweight debris items (paper, fiberglass, and plastic) are located near the ground surface at the bottom of the slope.

Quaternary Deposits

Native soils (Qcol) were encountered at test pits BB1TP104 and -103 on the slopes and in soil borings west of the Batteries (BB1SB102-104 and -105). Soil logged in the bluff top borings is interpreted to

represent Colma formation. The soils mapped on the slope of BBDA-1 may represent colluvium or mobilized residual soils derived from serpentinite bedrock.

Bedrock

Based on observations made of bedrock outcrops and bedrock encountered in test pit excavations on the BBDA-1 slopes, the upper portions of the slopes are underlain by serpentinite, while the lower portion is underlain by a combination of Franciscan Mélange and serpentinite. The nature of the contact between these two bedrock units is shown in cross-sections A-A' and C-C' (Figure 5) as near vertical and striking north. The following provides a description of the two rock units at BBDA-1:

- Serpentinite – In outcrop, the rock is hard, strong, and most competent near the top of the slope. East of Battery Boutelle, the rock is intensely fractured and deeply weathered, as indicated by Borings BBSB102, 104, and 105. In the sloping portion of the bluff, the serpentinite is also deeply weathered (Test Pits BB1TP103 and –TP105) but the depth of weathering is uncertain because of the limited penetrations made into rock.

- Mélange – Based on logging of test pits BB1TP102 and -106, this rock unit is black, intensely fractured, weak to friable, and of low hardness. It contains serpentinite rock fragments and is moderately to deeply weathered. Surface outcrops generally comprise mudstone and sheared sandstone with locally friable and crushed sandstone blocks.

Groundwater

Saturated conditions were observed in some test pits BB1TP103, -102, and -106 and in piezometers BB1PZ100 and BB1PZ101, and are attributed to seepage observed near the base of the slope. Water levels were measured in May, August, October of 2005, and February 2006, and are presented in Table 4. Water levels in BB1PZ100, which is screened in bedrock, have generally been consistent over the monitoring period, suggesting that the seep may be perennial. Water levels in BB1PZ101, which is screened in waste fill, have fluctuated over the monitoring period.

The seep is located in the thickest area of waste fill, and based on water level measurements in BB1PZ101, approximately 5 to 6 feet of saturated waste fill material present in this area during the dry (summer) months. Based on this observation as well as those made during excavation of test pit BB1TP102, it is expected that during remediation, this seep will produce approximately 18 to 20 gallons per minute (gpm) of water and excavation dewatering will be required in this area. Estimated seep rate calculations are provided in Appendix J.

Results of Analytical Testing – 2005 Field Investigation

During the 2005 field investigation, soil samples were collected and analyzed from two beach locations, one boring, one cultural resource trench, and two test pits in BBDA-1 (BB1SB113, BB1SB114, Trench 5, BB1SB110, BB1TP102, BB1TP109, and BB1TP106) at depths ranging from 0.5 to 7 ft bgs. In addition, a sample was collected from incinerator waste that appeared to contain ash (BB1TP108(5.0)). Borings, sample numbers, and sample depths are shown in Tables 1 and 17. The location of the trenches, test pits, and soil borings are shown on Figure 5. The results of chemical concentrations were compared with applicable clean-up levels, listed in Table 5. The detected results are presented in Tables 7A, 7B, 8A, and 8B.

Metals and PAHs were detected at concentrations exceeding applicable cleanup levels. Dioxins and furans were detected in the sample collected from incinerator waste [BB1TP108(5.0)]. The calculated toxic equivalency value (TEQ) for 2,3,7,8-tetrachlorodibenzo-p-dioxin (2,3,7,8-TCDD) of 0.0002638

mg/kg exceeded the RWQCB residential environmental screening level (ESL) of 0.0000045 milligrams per kilogram (mg/kg) and the Environmental Protection Agency (EPA) preliminary remediation goal (PRG) of 0.0000039 mg/kg for 2,3,7,8-TCDD (Table 18). Dichlorodiphenyltrichloroethane (DDT), dieldrin, endrin, endrin aldehyde, PCB 1254, PCB 1260, methylene chloride, arsenic, barium, cadmium, copper, lead, selenium, silver, and zinc were identified COCs for BBDA-1 in the RAP (*MACTEC, 2004b*). Based on the most recent sampling results, antimony, mercury, molybdenum, vanadium, chlordane, benzo(a)anthracene, benzo(a)pyrene, dibenzo(a,h)anthracene, TPH diesel and TPH motor/fuel oil, and dioxins and furans detected in the incinerator waste sample are also considered COCs for BBDA-1. Results for these COCs are shown on Figure 5.

As discussed in Section 3.6.4, in May and August 2005, groundwater samples were collected from BB1PZ101. Initially, only BB1PZ101 was sampled because BB1PZ101 is screened in waste fill and therefore was considered to be more likely to contain contaminants derived from debris disposed at the site than would water samples from BB1PZ100, which is screened in native soil. Samples collected in May 2005 were analyzed for VOCs, PAHs, dioxins and furans, TPH as gasoline, diesel, and motor/fuel oil, pesticides, PCBs, and dissolved metals. Samples collected in August 2005 were analyzed for dissolved Title 22 metals (field filtered sample) and total Title 22 metals (unfiltered sample). Results are presented on Table 9; the unfiltered sample was assigned a 'UF' designation at the end of the sample ID.

Analytical results were compared to surface water, freshwater seep, and drinking water cleanup levels presented in EKI, 2002 and RWQCB, 2004. Only copper and lead concentrations (60 and 45 micrograms per liter [µg/L], respectively) in the unfiltered sample exceeded surface water cleanup levels. Review of the cleanup level document shows that these cleanup levels were based on dissolved metals concentrations and are therefore not applicable to unfiltered samples. Comparison of results to drinking water cleanup levels shows that only arsenic in the unfiltered groundwater sample (13 µg/L) exceeds the drinking water cleanup level of 10 µg/L, which is also only applicable to filtered water samples.

Results of Additional Analytical Testing – February 2006 Field Investigation

During the February 2006 field investigation, soil samples were collected at 0.5 and 1 ft bgs from BB1SB115 and analyzed for Title 22 metals to verify metals concentrations previously detected in RI boring BBSB05 (Figure 5). RI Boring BBSB05 was located in an area mapped as native soil downslope of BBDA-1 waste fill. Sample IDs and sample depths are listed in Tables 1 and 17. Analytical results were compared to applicable cleanup levels listed on Table 5. The detected results for BB1SB115(0.5) and BB1SB115(1.0) are presented in Tables 7A and 7B.

Metals (arsenic, copper, selenium, and zinc) were detected in the soil samples from BB1SB115 at concentrations exceeding applicable cleanup levels. Results of the February 2006 sampling confirm the presence of metals above cleanup levels at RI Boring BBSB05 and indicates that soil adjacent to and downslope of the waste fill has been impacted by past site disposal practices.

As discussed in Section 3.6.4, in February 2006, groundwater samples were collected from BB1PZ101 and BB1PZ100. Samples collected in February 2006 were analyzed for VOCs, PAHs, TPH as gasoline, diesel, and motor/fuel oil, pesticides, PCBs, dissolved metals (field filtered sample), total metals (unfiltered sample), and general minerals. Results are presented on Tables 9A, 9B, and 9C.

Analytical results were compared to the most stringent of drinking water, freshwater seep, and surface water cleanup levels. Comparison of results to these cleanup levels shows that TPH motor/fuel oil (C24-C36), chrysene, antimony, arsenic, cadmium, chromium, copper, lead, mercury, nickel, selenium, and zinc exceed cleanup levels. Only unfiltered samples exceeded cleanup levels for arsenic cadmium, chromium, lead, nickel, and zinc and those cleanup levels are values from RWQCB 2005, which are based on dissolved metals concentrations and are therefore not applicable to unfiltered samples. It is

noted that the sample collected from the piezometer screened in native soil contained the highest concentrations of TPH. Mercury was detected at concentrations above cleanup levels in all samples except for the primary sample from the deeper piezometer. Antimony results are suspect because the only samples showing antimony above cleanup levels were filtered water samples; the unfiltered samples collected from the same piezometers showed lower concentrations. Based on the results of the February 2006 sampling, there are elevated levels of contaminants (TPH, mercury, and selenium) in the seep water and the water will require containment during the remedial construction phase and cannot be discharged at the site (Tables 9A and 9B).

Results of the general minerals analyses shows that groundwater in the piezometer screened in fill (BB1PZ101) and in the piezometer screened in weathered bedrock/native soil (BB1PZ100) are both sodium bicarbonate groundwater types. Comparison of other general minerals shows that iron, calcium, magnesium, and manganese concentrations are higher and fluoride, total dissolved solids (TDS), and chlorine concentrations are lower in BB1PZ100 than in BB1PZ101. Sodium, nitrate, sulfate and bromide concentrations are similar between the two wells (Tables 9C and Figure 10).

The general minerals data (Table 9C) do not necessarily indicate that the surface water in the seep (represented by water samples from Piezometer BB1PZ101) is derived from groundwater (represented by water samples from BB1PZ100) because several metals including magnesium, iron, calcium, and manganese were detected at higher concentrations in BB1PZ100 than in BB1PZ101. The chloride:bromide ratios are different in samples from the two piezometers, supporting that water in the two piezometers are from different sources; e.g., surface water in BB1PZ101 and groundwater in BB1PZ100. Additional sampling should be performed to further evaluate groundwater chemistry conditions at the site.

Nature and Extent of Contamination

This section presents an evaluation of the nature and extent of contamination at BBDA-1 based on the results of investigations conducted at the site to date.

Previous investigations have primarily focused on characterizing waste fill. However, historic fill was also evaluated as part of the investigation described in this document. Review of geologic maps and boring and trench logs indicates that at the top of the bluff, waste fill overlies historic fill, which is underlain by native soil, which in turn is underlain by serpentinite. On the bluff slope, waste fill lies on top of serpentinite or Franciscan mélange. Waste fill ranges from 2 to 12 feet thick and historic fill is up to 15 feet thick at the bluff top. Lithologic logs show that waste fill contains household, construction, and incinerator waste. Based on the trench logs, incinerator waste appears to be present primarily in the northern portion of BBDA-1. The mapped extent of the waste fill and cross sections illustrating the relationship between the fill units and native soil and bedrock are provided on Figure 5.

Figure 5 posts COCs detected in soil above applicable cleanup levels. These COCs include metals, pesticides, PCBs, PAHs, and dioxins and furans which reflect the types of wastes disposed in the area. Review of these data shows that both historic fill and waste fill samples contain COCs above cleanup levels, and that the waste fill has differing chemical signatures than the historic fill. More COCs were detected above cleanup levels in the waste fill than in the historic fill and with the exception of dieldrin, COC concentrations were significantly higher in the waste fill. Four COCs were detected above cleanup levels in the historic fill whereas twenty-three COCs were detected above cleanup levels in the waste fill samples. It should be noted that the samples of historic fill containing COCs above cleanup levels were collected beneath the waste fill in the vicinity of the former incinerator and are likely affected by waste burning and disposal practices in that area. This includes samples collected from historic fill that contain pesticides and PAHs above cleanup levels.

Three samples were collected from native soil overlying material mapped as Franciscan mélange downslope of a mapped waste fill area (BBSB05, BB1SB115). Comparison to site cleanup levels, which are based on background concentrations for serpentinite, shows exceedances of cleanup levels for arsenic, antimony, copper, selenium, mercury, vanadium, and zinc. Because there are no background levels for this soil type, it is not known if these concentrations represent background concentrations or are related to contamination from past site disposal practices. Because the area is located immediately downslope of the waste fill area, soil in this area is considered to be impacted by contaminants from the waste fill.

One surface soil sample was collected from native soil at BBSB103 north of the waste fill area adjacent to Battery Marcus Miller. Benzo(a)pyrene (0.23 milligrams per kilogram [mg/kg]) and dibenzo(a,h)anthracene (0.082 mg/kg) were detected above cleanup levels in the sample collected from this boring. The PAHs detected in this sample may be derived from fragments of asphalt/tar roofing material that have shed off of the adjacent battery.

Methylene chloride was detected in 0.5-foot samples collected from borings BB1SB113 and BB1SB114 at (J) estimated values of 0.150 and 0.120 mg/kg. It should be noted that because methylene chloride was not detected in the laboratory blank sample, these results were not qualified as not detected. These were shallow soil samples that were collected from beach dune sand below debris. No other COCs were detected above cleanup levels. These estimated values exceed the cleanup level for methylene chloride. These methylene chloride results appear suspect for the following reasons:

- Methylene chloride is a common laboratory contaminant.
- No other COCs were detected above cleanup levels.
- It is highly unlikely that methylene chloride would be present at elevated concentrations in sand impacted by wave and tidal action.

The following table shows the maximum detected concentration of COCs detected above cleanup levels in the historic fill, waste fill, and native soil at BBDA-1.

Maximum Detected Concentration of COCs Detected Above Cleanup Levels in BBDA-1

	Historic fill		Waste Fill		Franciscan Melange		Cleanup Level
COC	Maximum Concentrations in mg/kg	No of samples exceeding Cleanup level/No of Samples Analyzed	Maximum Concentrations in mg/kg	No of samples exceeding Cleanup level/No of Samples Analyzed	Maximum Concentrations in mg/kg	No of samples exceeding Cleanup level/No of Samples Analyzed	mg/kg
Arsenic	6.6	1/3	230	5/15	14	2/3	5.4
Antimony			123	6/14	100	1/3	5
Barium			2500	5/15			320
Cadmium			28	8/15			1.9
Copper			2200	4/15	130	1/3	85
Lead			6000	18/38			160
Silver			140	6/15	2.63	1/3	2
Selenium			2.2	7/14	2.37	1/3	0.5
Mercury			7.7	4/15			0.4
Molybdenum			84	2/6			12

COC	Historic fill		Waste Fill		Franciscan Melange		Cleanup Level
	Maximum Concentrations in mg/kg	No of samples exceeding Cleanup level/No of Samples Analyzed	Maximum Concentrations in mg/kg	No of samples exceeding Cleanup level/No of Samples Analyzed	Maximum Concentrations in mg/kg	No of samples exceeding Cleanup level/No of Samples Analyzed	mg/kg
Vanadium			110	3/15	99.4	1/3	74
Zinc			73000	20/35	370	1/3	160
TPH Diesel			780	1/5			
TPH motor/ fuel oil			3500	1/5			980
Methylene chloride			0.23	4/13			0.076
DDT	0.052	1/3	0.39	7/12			0.0082
Dieldrin	0.073	1/3	0.06	5/12			0.03
Endrin			0.005	1/12			0.004
Total chlordane			0.0215	1/13			0.009****
PCBs			0.43	3/16			0.033
PAHs (benzo(a) pyrene)*	0.037	1/3	0.33	3/7			0.027
Dioxins and Furans (2,3,7,8-TCDD TEQ)	0.00026388	1/1					0.0000045** 0.0000039***

*Other PAHs were detected above cleanup levels. The maximum concentration of benzo(a)pyrene is shown to represent PAH contamination.

**RWQCB residential ESL.

*** EPA Region IX residential PRG.

****Cleanup level is for total chlordane; detected results for alpha and gamma chlordane are summed for comparison to cleanup level.

Based upon lithologic and chemical characterization data, it appears that the area mapped as waste fill contains COCs above cleanup levels and requires remediation. It also appears that historic fill underlying the waste fill in the vicinity of the former incinerator also contains COCs above cleanup levels and should be removed. The incinerator waste contains dioxins and furans and should be sampled and handled in accordance in accordance with DTSC guidance for investigation and characterization of Burn Dumps. The depth of contamination varies from 2 to 12 feet based on the thickness of the waste fill. It should be noted that no samples have been collected from perimeter areas to confirm that native soils do not contain COCs above cleanup levels. However, it is expected that based on the nature of the source material (solid waste) and contaminants that are not highly mobile, contamination is not expected to extend beyond the mapped limits of the waste fill.

6.2.2 Baker Beach Disturbed Area-1A

BBDA-1A is the smallest of the debris areas. It occupies a sloping area north of BBDA-1 and west of Battery Marcus Miller. Access is to the area is limited to the bluff-top trail. Elevations range from 165 to 180 ft, and the inclination of the slopes ranges from 24 to 30 degrees. Vegetative cover consists of a mix of mature trees and shrubs, with patches of groundcover.

Artificial Fill

BBDA-1A contains a thin (less than 2 feet) horizon of waste fill, consisting of asphalt pieces, brick fragments, and chunks of tar. Scattered asphalt (roof covering of Battery Marcus-Miller) was also observed within the debris area. Historical fill underlies the waste fill and consists of grey silty sand with occasional serpentinite cobbles. This material represents older historical fill (afh1) likely derived from pre-Endicott construction. Colma soils (native material) are present beneath the outer (westward) edge of the artificial fill.

Quaternary Deposits

Quaternary deposits were observed in test pit BB1A-TP100 only, beneath the historic fill and are 3 feet thick. The soils are slightly cemented silty sands of the Colma formation and are medium dense. A wedge of Colma sand extends further down the slope and beyond the limits of BBDA-1A.

Bedrock Material

Serpentinite bedrock was observed within test pit excavations on the BBDA-1A slopes at depths ranging from 5 to 7 feet. Surface exposures of mélange bedrock were generally poor. The nature of the contact between these two bedrock units is presented in cross-section G-G' (Figure 6). The rock is medium hard, weak to hard, and becomes intensely fractured, friable, and of low hardness to the east of Battery Marcus Miller (Boring SBSB100).

Groundwater

Saturated conditions were not noted in borings or test pits for BBDA-1A. It is possible that perched groundwater may occur during the wet season, as seepage was observed downslope at BBDA-1.

Results of Analytical Testing – 2005 Field Investigation

During the 2005 field investigation, two soil samples were collected and analyzed from one test pit at BBDA-1A (BB1ATP101) at depths ranging from 0 to 3 feet bgs. Sample numbers and sampling depths are shown in Tables 1 and 17, and the location of the test pit is shown on Figure 6. Analytical results are presented in Tables 10A and 10B. The *Remedial Action Plan (*RAP; *MACTEC, 2004b*) identified heptachlor epoxide, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, and indeno(1,2,3-c,d)pyrene as COCs for BBDA-1A. Analytical results for these COCs are presented on Figure 6.

Nature and Extent of Contamination

This section presents an evaluation of the nature and extent of contamination at BBDA-1A based on the results of investigations conducted at the site to date. Geologic maps and trench logs indicate that at BBDA-1A, displaced historic fill overlies waste fill. The fill overlies native soil that in turn overlies serpentinite. Waste fill is approximately one to two feet thick and dominantly comprises asphalt, brick, and tar. It appears that the roofing material was scraped from Marcus Miller onto the battery apron, based on historical information. The mapped extent of the waste and historic fill and cross sections illustrating the relationship between the fill units, native soil, and bedrock are provided on Figure 6. Only six samples have been collected from four locations at the site for chemical analysis; one of these samples was collected from historic fill, the other five samples were collected from waste fill. Figure 6 posts COCs detected in soil above cleanup levels. Only two waste fill samples collected from one boring contain COCs (PAHs and pesticides) at concentrations exceeding cleanup levels. PAHs are expected based on the asphalt and tar debris found at the site. The following table shows the maximum detected concentration of COCs detected above cleanup levels at BBDA-1A.

Maximum Detected Concentration of COCs Detected Above Cleanup Levels at BBDA-1A

COC	Waste Fill		Cleanup Level
	Maximum Concentrations in mg/kg	No. of samples exceeding Cleanup level/ No. of Samples Analyzed	mg/kg
Benzo(a)anthracene	0.6	1/6	0.27
Benzo(b)fluoranthene	2	1/6	0.27
Benzo(a)pyrene	2	1/6	0.027
Indeno(1,2,3-cd)pyrene	2	1/6	0.27
Heptachlor epoxide	0.023	1/6	0.017

Based on material observed in test pits and on the ground surface at the site, it appears that waste fill mapped at the site contains COCs above cleanup levels and requires remediation. The contact between the waste and historic fill provides a boundary for the vertical extent of contamination because a sample collected from historic fill material does not contain COCs above cleanup levels. Although no samples have been collected for chemical analysis from areas outside the limits of the waste fill, based on the relative low mobility of contaminants found, contamination is not expected to extend beyond the mapped limits of the waste fill.

6.2.3 Baker Beach Disturbed Area-2

Surface Conditions

BBDA-2 is the southernmost of the BBDAs, and is located southwest of Battery Godfrey near the slope face. A gravel parking lot connects with BBDA-2 and the Covered Way around the southwest portion of Battery Godfrey. The terrain is relatively flat, with occasional hummocky areas south of the parking area. This area was graded for public access in the 1970s. Surface runoff is towards the edge of the bluff. The debris portion of BBDA-2 is predominately located down a steep slope to the west and in non-contiguous pockets to the south, surrounding former Magazines 27, 28, and 29, and metal salvage slabs. Elevations range from 185 to 255 feet over a lateral distance of 80 to 120 feet from the parking lot down to the top of a very steep escarpment. Below the escarpment are a series of vertical to near vertical slopes of bare bedrock. The bedrock slopes are generally devoid of any vegetation with the exception of scrub and perennial serpentine-type ground cover. Above the escarpment, mature trees, thick brush, and vines characterize the vegetative ground cover. Social trails extend from the parking lot down to the beach.

Artificial Fill

The exposures observed in the test pits and cultural resources trenches show a 3-dimensional image of wedges of waste fill, historic fill, and native soils that suggests successive dumping events. The fill is generally composed of very dark brown, organic-rich layers of coarse and fine grained soils. Construction debris (bricks, cobbles, concrete tile, waste rock), landscape debris (pockets of tree-trimmings), and a significant trash component (cans, bottles, chain-link fence, tire, wood box, glass) are present in the waste fill. The fill is generally less than 10 feet thick, and diminishes in thickness with distance from the cliff edge and a majority appears to rest upon native soils shown on Figure 7 (Geologic Cross section E-E).

Quaternary Deposits

Relatively thick deposits of yellow brown sandy clays and silts were observed in test pits, trenches, and borings. Between 3 and 6 feet of stiff to very stiff colluvium and Colma formation soils were logged in test pits excavated at BBDA-2. The Quaternary deposits are interpreted to thicken to the west and outcrop downslope of BBDA-2. They directly underlie waste fill, and overlie serpentinite bedrock and may represent residual serpentinite soil.

Bedrock Material

Bedrock was encountered between 6 and 20 feet bgs. Based on the surface exposures and test pit excavations on the BBDA-2 slopes, the upper portion of the slopes are underlain by serpentinite, as shown in cross-section E-E' (Figure 7). The rock variation is moderately hard and strong (Boring BB2SB100 and Test Pit BB2TP100) to more weathered and weaker (Borings BB2SB101, BBSB107, and Trench 1).

Groundwater

Groundwater was not observed in BBDA-2 test pits or trenches. Perched conditions may exist during the wet season if water were to collect on top of the bedrock surface.

Results of Analytical Testing – 2005 Field Investigation

Soil samples were collected and analyzed during the 2005 field investigation from three soil borings and two cultural resource trenches at BBDA-2 at depths ranging from 0 to 15 feet bgs. Boring, test pit, sample numbers, and sample depths are presented in Tables 1 and 17. Trench and soil boring locations are shown on Figure 7, and analytical results are presented in Tables 11A and 11B.

Metals were detected at concentrations exceeding applicable cleanup levels. Copper, lead, zinc, PAHs (benzo[a]anthracene, benzo[a]pyrene, benzo[b]fluoranthene, benzo[k]fluoranthene), Dichlorodiphenyldichloroethylene (DDT), and endrin were identified as COCs for BBDA-2 in the RAP (*MACTEC, 2004b)*. Based on results of the 2005 sampling, arsenic, barium, mercury, selenium, dibenz(a,h)anthracene, and indeno(1,2,3-c,d)pyrene, are also considered COCs for BBDA-2. Results for these COCs are posted on Figure 7.

Results of Additional Analytical Testing – February 2006 Field Investigation

Soil samples were collected from BB2SB110 at 0.5 and 1 feet bgs and analyzed for Title 22 metals to confirm previously detected concentrations of cadmium and selenium in soil samples from RI boring BBSB07. These samples were collected from areas mapped as native soil/colluvium. Sample identification numbers, sample depths, and requested analyses are presented in Tables 1 and 17. Trench and soil boring locations are shown on Figure 7, and analytical results are presented in Tables 11A and 11B.

Arsenic was detected at 5.6 mg/kg in one of the three samples collected from the boring at concentrations exceeding the cleanup level of 5.4 mg/kg, which is based on the background level for serpentinite soil. It is noted that the detected concentration is less than the background level for Colma formation soil of 6.2 mg/kg; Colma formation is present at the site but was not separately mapped from colluvium and residual serpentinite soil. Selenium was also detected at concentrations ranging from 0.98 to 1.3 mg/kg which exceeded the cleanup level of 0.5 mg/kg. The cleanup level is based on the background level for serpentinite soil, which was set as the detection limit for selenium in the background dataset. These

results confirm previous result for selenium of 1.29 mg/kg in BBSB07, but do not confirm the previously detected concentration of cadmium at 2.2 mg/kg (Figure 7).

Nature and Extent of Contamination

This section presents an evaluation of the nature and extent of contamination at BBDA-2 based on the results of investigations conducted at the site to date. Geologic maps and boring and trench logs indicate that at the top of the bluff at BBDA-2, 5 to 15 feet of historical fill overlies native soil or native serpentinite rock. On the bluff slope, 1.5 to 8 feet of waste fill overlies a wedge of displaced historical fill. Where the underlying historical fill is absent, the waste fill overlies native soil. In the middle of the site, it appears that displaced historical fill lies upon the waste fill. At BBDA-2, the waste consists of bricks, cobble, concrete tile, and trash. The mapped extent of the waste and historic fill and cross sections illustration the relationship between the fill and native soil and bedrock units are provided on Figure 7.

Soil samples have been collected for chemical analysis from waste fill, historic fill, and native soil underlying the fill deposits. Four soil samples were also collected from borings BBSB108 and -109 located in the vicinity of the former metals recycling and disposal areas; these samples were collected from undisturbed historic fill and native serpentinite. In addition, two samples collected from native soil downslope of the debris area and one sample collected from weathered serpentinite that underlay historic fill were also chemically analyzed. Figure 7 posts COCs detected in these soil samples above cleanup levels; these COCs include metals, pesticides, and PAHs.

Detected contaminants are consistent with the type of waste disposed in the area, use of the site for metals recycling and disposal, as well as vehicle use associated with the metals recycling area. With the exception of the surface soil sample collected in the metals disposal area (BBSB109 at 0 feet), COC concentrations in the waste fill are higher than the historical fill.

Soil samples collected from native soil and weathered serpentinite [BBD2TP105(15), BBSB07(0.0), BB2SB110(0.5), BB2SB110(1.0), BBSB108(2)] contain arsenic, selenium, and/or cadmium concentrations above cleanup levels, which are based on background levels for serpentinite soils of 5.4, 0.5, and 1.9 mg/kg, respectively. BBD2TP105(15) and DUP020106 contained arsenic at 5.8 and 5.6 mg/kg which is below background for Colma formation (5.9 mg/kg) and therefore, arsenic at those locations are not believed to be the result of waste disposal practices at the site. The sample that contained arsenic at 10 mg/kg soil [BBD2TP105(15)] was collected in the vicinity of a former metals salvage shop and may be present in soil as a result of past site use for metals recycling. Only one sample BBSB07(0.0) contained cadmium at 2.2 mg/kg, which exceeded background of 1.9 mg/kg. The cadmium results were not confirmed by subsequent soil samples collected from adjacent boring BB2SB110. Selenium was detected above the background level in five of the native soil samples at a maximum concentration of 1.3 mg/kg, exceeding the cleanup level of 0.5 mg/kg. As previously discussed, the background value for selenium is based on the detection limit. Most of the exceedances of selenium were reported in samples from BBSB07 and BB2SB110 which are not apparently near waste debris. It is possible that these selenium levels do not represent site contamination because there may be local variations in native metals concentrations that are not captured by the background metals dataset.

The following table shows the maximum detected concentration of COCs detected above cleanup levels in the historic fill, waste fill, and native soil or serpentinite at BBDA-2.

Maximum Detected Concentration of COCs Detected Above Cleanup Levels in BBDA-2

	Historic fill		Waste Fill		Native Soil/Serpentinite		Cleanup Level
COC	Maximum Concentration in mg/kg	No of samples exceeding Cleanup level/No of Samples Analyzed	Maximum Concentration in mg/kg	No of samples exceeding Cleanup level/No of Samples Analyzed	Maximum Concentration in mg/kg	No of samples exceeding Cleanup level/No of Samples Analyzed	mg/kg
Arsenic	7.4	2/7			10	3/7	5.4
Barium			520	1/7			320
Cadmium					2.2	1/7	1.9
Selenium			0.541	1/7	1.3	5/7	0.5
Copper			118	1/7			85
Lead	1900	3	210	2/7			160
Mercury	1.1	2/7	0.49	1/7			0.4
Zinc	210	3/7	420	3/7			160
DDT			0.02	1/7			0.0082
Endrin			0.006	1/7			0.004
PAHs (benzo(a)pyrene)	0.082	2/6	.14	3/3			0.027

Based upon lithologic and chemical characterization data it appears that waste fill and displaced historic fill contain COCs above cleanup levels and requires remediation. The depth of contamination varies from 2 to 8 feet depending on the thickness of the waste and displaced historic fill. Of the two samples collected from native soil beneath the fill, only one sample contains COCs above cleanup levels - arsenic at 5.8 mg/kg, just above the cleanup level and background threshold level for arsenic in serpentinite of 5.4 mg/kg. The one perimeter sample collected at the site (BB2SB102) shows PAHs (benzo(a)pyrene) in surface, but not deeper soil (2 feet bgs) in this area.

Undisturbed historical fill in the vicinity of the former metals recycling and disposal area also contains metals and PAHs above cleanup levels and requires remediation. Analytical results from Boring BBSB108 indicates that contamination extends to at least 2 feet bgs in this area. However, comparison of results for the sample and duplicate sample collected at 2 feet bgs at BBSB109 suggests that the presence of lead at depth is not extensive (e.g., lead concentration was 1,900 mg/kg at the surface, and was 35 and 180 mg/kg in the sample and duplicate sample, respectively, at 2 feet bgs). No perimeter samples have been collected to characterize the areal extent of contamination in this area, but is expected that contamination will be in the general area where metals disposal and recycling operations were performed.

Selenium, cadmium, and arsenic have been detected above background in an area (BBSB07 and BB2SB110) where no waste fill or historic fill has been identified. Based on the magnitude of the metals exceedances at that location, it is not recommended that soil be removed from this area.

6.2.4 Baker Beach Disturbed Area-2A

Surface Conditions

BBDA-2A, located north of BBDA-2, is a large, elongated debris area that extends westward from the gravel parking lot located adjacent to BBDA-2. The debris area extends down the slope a lateral distance of approximately 300 feet towards the beach, and is situated in a concave bowl. Vegetation consists of

grasses, shrubs, brush, and a few trees. Elevations range from near sea level to 255 feet. The uppermost portion consists of a prominent bedrock cliff, approximately 25 feet high, decreasing to an average slope inclination of 44 degrees. Erosion scars on the southern border are evident where surface drainage has been allowed to run down the slope.

Artificial Fill

The fill material varies widely in thickness and type, with stratification evident in trenches excavated across the slope. The waste fill layer is greater than 14 feet thick in the southern portion of BBDA-2A, decreasing in thickness towards the northern portions of the site. Debris encountered includes metal (auto parts, cable, cable spools, I-beams, sheet metal, and rebar), household items (glass, bottles, porcelain, and charcoal), and construction debris (concrete, brick, slate, marble, lumber, large logs, cobbles, and metal fence posts). The debris is concentrated in the upper layers of soil in a matrix of dark brown-grey sandy silt, which is rich in organic matter, and appears to be topsoil. Based on these observations, the fill was placed here as debris, and not as a debris/soil mixture. Although test pits BB2ATP101 and -TP104 did not extend down to bedrock, layers of bricks were encountered beneath the layers of trash debris. This may be representative of episodic disposal of brick debris related to the periodic demolition of structures, or a single disposal episode followed by a movement/sliding of debris after it was placed on the slope. Light brown siltstone gravel fill is present beneath the brick debris.

Quaternary Deposits

Native soils indicative of weathered serpentinite, and to a lesser extent colluvium and Colma formation, were observed in relatively thin layers (2 feet) in most of the test pits excavated at BBDA-2A. Soft to very dense, these clayey soils are locally sandy. Native soil has been observed on the bluff top and on slopes.

Bedrock Material

- Serpentinite – Logs of test pits show that the rock is hard, strong, and most resistant near the top of the slope near Battery Godfrey; the rock is relatively weak and deeply weathered, and becomes intensely fractured, friable, and of low hardness further down the slope.

- Mélange – Based on logging of test pits BB2ATP105 and -TP106, this rock unit is black, intensively fractured, weak and of low hardness. Surface outcrops are generally mudstone and sheared sandstone, with locally friable and crushed sandstone blocks.

Excavations of waste fill from BBDA-2A will leave relatively uniform, yet steep slopes in the exposed serpentinite. The mélange is less stable and may exhibit localized sloughing and/or seepage on the lower portions of the slope.

Groundwater

Saturated conditions in BBDA-2A were noted in test pits at 8 to 10 feet bgs. During the 2005 field investigation, a natural seep, which was not identified during previous investigations, was encountered and mapped at a location near the toe of the slope. This seep was sampled during the February 2006 field investigations. Analytical results for the samples collected from this seep are discussed below and presented in Tables 9A, 9B and 9C.

Results of Analytical Testing – 2005 Field Investigation

Soil samples were collected and analyzed during the 2005 field investigation from one beach location, three soil borings, one cultural resource trench, and three test pits at BBDA-2A. Sampling depths ranged from 0.5 to 14 ft bgs. Test pits, soil borings, sample numbers, and sample depths are presented in Tables 1 and 17. Trench, test pit, and soil boring locations are shown on Figure 8, and analytical results are presented in Tables 12A and 12B.

Metals (copper, mercury, silver, and zinc), PAHs (benzo[a]pyrene, benzo[b]fluoranthene, dibenz[a,h]anthracene, indeno[1,2,3-c,d]pyrene), and TPH motor/fuel oil were the only analytes detected at concentrations greater than applicable cleanup levels. PAHs (benzo[a]pyrene, benzo[b]fluoranthene, benzo[k]fluoranthene, dibenz[a,h]anthracene, indeno[1,2,3-c,d]pyrene), DDT, and metals (antimony, arsenic, barium, cadmium, copper, lead, mercury, selenium, and zinc) were previously identified in the RAP (*MACTEC, 2004b*) as COCs for BBDA-2A. Based on results of the 2005 sampling, silver and TPH motor/fuel oil are also considered a COC for this site. Figure 8 presents analytical results for BBDA-2A COCs.

Results of Additional Analytical Testing – February 2006 Field Investigation

In February 2006, a soil sample was collected at a depth of approximately 1 foot bgs from BB2SB120 and analyzed for PAHs and metals. The sample was collected adjacent to BBSB106 where PAHs and zinc had been detected above cleanup levels in a sample collected at 0.5 feet bgs. The two borings were drilled on the frontal slope of Battery Godfrey where fragments of asphalt roofing material were observed on the ground surface. The soil sample number, sample depth, and requested analyses are presented in Table 17. The sample location is shown on Figure 8, and analytical results are presented in Tables 12A and 12B.

Metals [selenium (0.58 mg/kg; cleanup level of 0.5 mg/kg) and vanadium (75 mg/kg; cleanup level of 74 mg/kg) were detected at concentrations just above applicable cleanup levels. PAH results were not detected or reported at concentrations below cleanup levels. It is noted that results for benzo(a)pyrene were qualified as not detected at a reporting limit of 0.064 mg/kg which exceeded the cleanup level of 0.027 mg/kg, therefore, the presence or absence of benzo(a)pyrene below cleanup levels at 1 ft bgs cannot be confirmed. During sampling, fragments of asphalt/tar roofing material were observed in the area. Based on results of the 2006 sampling, vanadium will also be considered a COC for this site. Figure 8 presents analytical results for BBDA-2A COCs.

As discussed in Section 3.6.4, in February 2006, surface samples were collected from a seep location at the base of BBDA-2A (BB2ASW100). Samples collected in February 2006 were analyzed for VOCs, PAHs, TPH as gasoline, diesel, and motor/fuel oil, pesticides, PCBs, dissolved Title 22 metals (field filtered sample) and total Title 22 metals (unfiltered sample). Results are presented in Table 9.

Analytical results were compared to the most stringent of drinking water, freshwater seep, and surface water cleanup levels. Comparison of results to these cleanup levels shows that benzo(a)anthracene, benzo(b)fluoranthene, chrysene, 4, 4’ DDT, antimony, arsenic, cadmium, copper, chromium, lead, mercury, nickel, selenium, and zinc exceeded cleanup levels. Only unfiltered samples exceed cleanup levels for arsenic, cadmium, chromium, lead, nickel, and zinc. Cleanup levels for these metals were based on levels presented in the RWQCB Basin Plan, which are based on dissolved metals concentrations and are therefore, not applicable to unfiltered samples. Antimony results are suspect because antimony was detected in the filtered but not the unfiltered water sample. Based on the results of the February 2006 sampling, it appears that there are elevated levels of selenium, mercury, and PAHs in the seep water that will require containment during the remedial construction phase and cannot be discharged at the site.

Nature and Extent of Contamination

This section presents an evaluation of the nature and extent of contamination at BBDA-2A based on the results of investigations conducted at the site to date. These investigations have primarily focused on characterizing waste fill and historic fill. Only one sample has been collected for chemical analysis from what is characterized as native soil and one soil sample has been collected from beach sand underlying beach debris.

Review of geologic maps, boring and trench logs indicates that at the top of the bluff, historic fill is underlain by native soils that are in turn underlain by serpentinite. On the bluff slope, waste fill sits upon displaced historic fill that is underlain by serpentinite and/or landslide debris. Lithologic logs indicate that the waste fill contains metal, household, and construction debris that is generally concentrated in the upper portion of the fill deposit. Depths of the waste fill vary from 2 feet near the bluff top (BB2ATP100 and -102) to thicknesses greater than 14 feet (BB2ATP101). The mapped extent of the waste fill and cross sections illustrating the relationship between the fill units, native soil, and bedrock are provided on Figure 8.

Figure 8 posts COCs detected in soil above applicable cleanup levels. These COCs include metals, DDT, and PAHs. Review of these data show that both historic fill and waste fill samples contain COCs above cleanup levels. Concentrations of metals generally appear to be higher in the waste fill. However, similar PAH concentrations were seen in both types of fill, and based on limited sampling, higher DDT concentrations were detected in the historic fill compared to waste fill soil samples. With two exceptions (BBSB106 and BBSB120), the historic fill containing COCs above cleanup levels comprised displaced historic fill that underlay or was in close proximity to waste fill. The soil samples from BBSB106 and BBSB120 were collected at 0.5 and 1 foot bgs on the frontal slope west of Battery Godfrey. These samples contained PAHs, selenium, vanadium, and zinc at concentrations of 0.34 (for benzo(a)pyrene), 0.58, 75, and 190 mg/kg, respectively which exceeded cleanup levels of 0.027, 0.5, 74, and 160 mg/kg and likely reflected contamination related to asphalt/tar roofing material present on the ground surface. This material appeared to have been derived from Battery Godfrey.

One sample was collected at 2 feet bgs from native soil just north of the mapped waste fill. The only COC present above cleanup levels in this sample was cadmium, which was detected at 3.0 mg/kg, which exceeded the background level of 1.9 mg/kg for cadmium in serpentinite soil. Because this was the only COC detected above cleanup levels, it is not clear if this detection represents contamination related to past site disposal practices.

One sample was also collected from beach sand underlying debris and submitted for chemical analysis. Only one COC, arsenic, was detected at a concentration (6.4 mg/kg) exceeding the cleanup level of 5.9 mg/kg which represents background for Beach Dune sand. Because the background dataset may represent the range of metals concentrations present in recent beach deposits, this exceedance may not represent contamination from past site-disposal practices. The following table shows the maximum detected concentration of COCs detected above cleanup levels in the historic and waste fill at BBDA-2A.

Maximum Detected Concentration of COCs Detected Above Cleanup Levels in the Historic and Waste Fill at BBDA-2A

COC	Historic fill		Waste Fill		Cleanup Level
	Maximum Concentration in mg/kg	No of samples exceeding Cleanup level/No of Samples Analyzed	Maximum Concentration in mg/kg	No of samples exceeding Cleanup level/No of Samples Analyzed	mg/kg
Arsenic	6.7	4/10			5.4
Barium			390	1/7	320
Cadmium			11	5/7	1.9
Selenium	1.2	2/10			0.5
Mercury	0.58	2/10			0.4
Silver	2.3	1/10			2
Copper	92	1/10	150	1/7	85
Lead	210	2/10	500	4/7	160
Vanadium	75	1/10			74
Zinc	270	4/10	720	3/7	160
DDT	0.12	4/8	0.06	3/5	0.0082
TPH Motor/Fuel oil		1/1			
PAHs (benzo(a)pyrene)	0.34	4/10	0.33	1/7	0.027

Based on lithologic and chemical analytical data, it appears that the area mapped as waste fill and the underlying and adjacent displaced historic fill contains COCs above cleanup levels and requires remediation. Based on trench logs, depending on the depth of the fill, it appears that contamination extends from 2 to over 14 feet bgs. It also appears that shallow soil in the frontal slope; west of Battery Godfrey also contains elevated levels of COCs. It is not expected that contamination in this area extends to depths greater than 2 feet in this area as the likely source of the contamination is asphalt/tar roofing material present on the ground surface in the area. It is noted that there are limited soil samples collected in perimeter areas to confirm that native soils do not contain COCs above cleanup levels. Based on the low mobility of the contaminants and the nature of the contamination source (debris fill), contamination is not expected to extend beyond the mapped limits of the waste fill or displaced artificial fill.

6.2.5 Merchant Road Area and Undesignated Disturbed Area

Surface Conditions

Merchant Road passes through the easternmost area of the project area. Most of this area consists of relatively flat to moderately sloping and wooded terrain. This area includes the land behind the bluff top, and is generally free of building structures with the exception of GGBHTD buildings east of Battery Marcus Miller (Figure 2). Merchant Road will be realigned prior to the remediation activities and will connect with Storey Road.

Existing, unpaved parking areas along the western shoulder of Merchant Road gently rise to a promontory at the eastern edges of a service road referred to as the Covered Way. This road was originally constructed in the early 1870s to serve gun emplacements at West Battery and is referred to as a "covered way," based on the assumption that it was constructed with high sides to protect it from enemy fire.

However, the road was not originally constructed as a feature below the surrounding ground level. When it was originally built, the road was at approximately the same elevation as the surrounding landscape. The area south of the "Covered Way" was raised as a result of grading activities associated with construction of the Endicott fortifications (i.e., West Battery materials that were pushed behind Batteries Godfrey and Marcus Miller.). The Covered Way represents the easternmost limits of the BBDAs, except where some waste fill was mapped near the GGBHTD offices (Figure 2). A bedrock knoll is located at the southernmost end of the Covered Way and represents the highest topographical point in the project area. The area is covered with trees, and contains the remnants of a concrete gunnery structure and a concrete building nestled in a depressed pit. An additional building is located to the northeast, adjacent to a parking lot.

An undesignated disturbed area is located east of the Covered Way and north of Battery Boutelle. This area has an irregular shape and is approximately 150 feet wide and 400 feet long. This area was identified based on a 1967 aerial photograph that showed piles of light colored fill in the area between the batteries and Merchant Road. The source of the fill is unknown; one potential source may have been excavations for the Letterman Hospital at the Presidio. Elevations range from 220 feet at the south to 190 feet at the north. The slopes are very gentle to the east towards Merchant Road, but are much more steep towards the Covered Way to the west. Brush, small trees, and grass cover most of the area. The GGBHTD offices are situated partly within and just north of the area. These buildings are shown on Figure 2.

Artificial Fill

The material encountered in test pits TP-110, -111, -112, and -113 indicates that the fill noted in the 1967 aerial photograph (discussed above) is between 2 and 6 feet thick, and ranges from a silty gravel with sand to a lean clay/silt with gravel. Debris found in the fill consists of concrete, bricks, tar cemented gravels, wood, automobile parts, charcoal, and metal and was limited to a small area on the western side of the disturbed area. Much of this debris is exposed along the back slope of The Covered Way. Other fill (afo) consisting of silty sand and lean clay without debris was observed between The Covered Way and Merchant Road.

Quaternary Deposits

The borings encountered yellowish brown sandy clays and silty sands, which are interpreted to be Colma formation and/or highly weathered bedrock or residual soil, based their gradational contact with the underlying serpentinite and the presence of faint relict foliation. These soils were between 4 and 6 feet thick.

Bedrock Material

Bedrock was not encountered in any of the test pits. However, soil borings were advanced to refusal in serpentinite bedrock at depths ranging from 7 to 10 feet bgs. This serpentinite bedrock appeared to be highly weathered and fractured.

Groundwater

Groundwater was not observed in any of the test pits or trenches.

Results of Analytical Testing – 2005 Field Investigation

During the 2005 field investigation, soil samples were collected and analyzed from 4 test pits and 3 borings (BBITP110, -111, -112, and -113) and BBSB117, -118, and -119 at depths ranging from 1.5 to 12 ft bgs. Test pits, borings, sample numbers, and sample depths are shown in Table 1. The location of

the trenches, test pits, and soil borings are shown on Figure 2. The results of chemical concentrations were compared with applicable cleanup levels, listed in Table 5. These cleanup levels are those considered applicable to portions of the BBDAs designated as ecological buffer zone areas (Figure 4A). The detected results are presented in Table 14A and 14B. TPH compounds, PCBs, PAHs, and pesticides did not exceed applicable cleanup levels for the site. VOCs were not detected. Arsenic was detected at concentrations exceeding applicable cleanup levels for serpentinite soil and have been identified as a COC. Results for this COC are shown on Figure 9.

Nature and Extent of Contamination

This section presents an evaluation of the nature and extent of contamination at the undesignated fill/Merchant Road area based on the results of the 2005 field investigation. Logs for test pit BB1TP113 indicate that just east of the Covered Way, approximately 3 to 4 feet of waste fill comprising silty gravel with sand, clayey sand, sandy silt containing tar-cemented gravels, concrete, wood, charcoal, and auto parts overlies native soil consisting of sandy lean clay. In the portion of the site that was designated as a fill area based on the 1967 aerial photograph, trench logs (BB1TP110, -111, and -112) show that approximately 2 to 7 feet of fill containing construction debris is present in the central and southern portions of the fill area. This fill appears to be dominantly composed of silt or clay with gravel, concrete, brick, asphalt, and wood. This fill overlies 1 to 7 feet of other fill, comprising sandy clay or silty sand with cobbles and serpentinite clasts. The fill overlies native soil consisting of sandy lean clay and silty sand.

Soil samples have been collected for chemical analysis from other fill and native soil underlying the fill deposits. Figure 9 posts chemicals detected in these soil samples above applicable cleanup levels (serpentinite soil/human health/ecological buffer zone). Based on this comparison, the only chemical detected above applicable cleanup levels is arsenic.

Arsenic was detected in several samples at concentrations ranging from 3.2 to 5.8 mg/kg. Three samples, two collected from native soil and one collected from waste fill, exceed the cleanup level of 5.4 mg/kg, which corresponds to the background concentration for arsenic in serpentinite soil. Review of lithologic logs indicate that the two native soil samples containing arsenic above 5.4 mg/kg were collected from soil which may represent Colma formation or soil that represents a combination of Colma and residual serpentinite soils. It should be noted that arsenic concentrations do not exceed the background concentration for Colma formation soils of 6.2 mg/kg. Scatter plots for the two samples collected from native soil BBTP111(6.0) and BB1TP110(12) show distribution of metals that are similar to Colma soils with possible contribution from the underlying serpentinite, supporting that these arsenic levels are likely naturally occurring concentrations. Scatter plots comparing site metals to data from the Presidio background dataset are presented in Appendix L.

The following table shows the maximum detected concentration of COCs detected above cleanup levels in the fill, waste fill, and native soil at the undesignated fill/Merchant Road Area.

Maximum Detected Concentration of COCs Detected Above Cleanup Levels in the Fill, Waste Fill, and Native Soil at the Undesignated Fill/Merchant Road Area

	Other fill		Waste Fill		Native Soil		Cleanup Level
COC	Maximum Concentration in mg/kg	No of samples exceeding Cleanup level/No of Samples Analyzed	Maximum Concentration in mg/kg	No of samples exceeding Cleanup level/No of Samples Analyzed	Maximum Concentration in mg/kg	No of samples exceeding Cleanup level/No of Samples Analyzed	mg/kg
Arsenic			5.8	1/1	5.8	2/4	5.4

Only cleanup level exceedances are cited.

Because the arsenic concentrations are within background for Colma formation soils, arsenic concentrations between 5.4 and 5.8 mg/kg are not considered to pose risk to human or ecological receptors. Therefore, because the waste fill in the central and southern portions of the site contains only construction debris containing brick and concrete and does not contain chemicals above cleanup levels, no remediation is recommended for soil in the central portion of the site.

Because the area of waste fill east of the Covered Way contains material (tar-cemented gravels, auto parts), that likely contain chemicals of concern above cleanup levels, it is recommended that this waste soil be removed. The impacted area is expected to be limited to the area mapped as waste soil and is expected to extend to 4 feet bgs, where native soils were encountered.

7.0 SLOPE STABILITY ANALYSES

This section presents the methodologies used and results of slope stability analyses to evaluate the coastal bluffs in the vicinity of Baker Beach Disturbed Areas 1, 1A, 2, and 2A. The purpose of the analyses was to assess the stability of the steep bluff slopes under existing conditions, during removal of waste fills and long term after remedial actions at the site are complete. Of particular concern are the potential effects of the planned waste removal on the stability of the historic batteries and other cultural features at the top of the bluff slopes.

7.1 Stability Study Methodologies

The stability of the existing and planned slopes was evaluated using soil and rock profiles and material properties determined from field exploration, geologic evaluation, and laboratory testing as described in the Material Properties Technical Memorandum (*MACTEC, 2005i*) and presented on Table 15. Eight subsurface profiles (A-A' through H-H') were selected for the stability analyses. The profiles are located as shown on Figure 2 and are presented in the cross-sections on Figures 5 through 8. The locations of the cross-sections were selected to model the steepest sections of each BBDA and to utilize the maximum amount of available subsurface information. The locations of the cross sections were also selected for stability analyses of the batteries, potential equipment and staging areas, and debris areas present near the base of the slopes.

The computer program Slope/W (Version 2004) by Geoslope International (*2004*) was used for the evaluation of circular and non-circular failure surfaces (Spencer's Method). The Infinite Slope Method was used for evaluation of shallow failures of frictional materials parallel to a slope. Both methods calculate a factor of safety, which is the ratio of the available resistance to sliding divided by the sliding forces The higher the factor of safety, the more stable the slope. Typically, a slope with a static factor of safety greater than 1.5 indicates a relatively stable slope. For short-term conditions, such as during construction, smaller factors of safety such as 1.3 are usually acceptable. Calculated factors of safety near 1.0 indicate that the slope may be on the verge of failure. Factors of safety well below 1.0 indicate that the slope analyzed would likely be unstable. For large earthquake loads, slope stability methods often yield factors of safety less than 1.0, indicating slope "failure". However, the effects of earthquakes on slopes can often be downslope deformation, rather than gross slippage of the "failure" mass.

The engineering properties of the fill materials, landslide debris, native soils/Colma Formation, and Franciscan bedrock were based on the results of our field investigation, laboratory testing, and engineering judgment, as described in our Materials Properties Technical Memorandum. The engineering properties used in the stability analyses are presented in Table 15.

7.2 Slope Stability Analyses of BBDAs

The results of the stability analyses are presented in Appendix D, and in Table 16, and are discussed below for the various areas of the site.

7.2.1 Baker Beach Disturbed Area 1

Cross-sections A-A', C-C', F-F' and H-H' are located within or near BBDA-1 (Figure 2) and are shown on Figure 5. Stability analyses of these sections indicate the following:

Existing Conditions

- The underlying Franciscan bedrock (mélange and serpentinite) are relatively strong and can be considered stable under short- and mid-term static conditions and earthquake conditions based on laboratory tests of the material and observations of exposed outcrops on the slope.

- The existing waste fills, historic fills, and native soils exposed on the steep slopes below the top of the bluff in BBDA-1 are marginally stable under static conditions based on calculated factors of safety typically near 1.0. In some very steep slopes, the calculated factors of safety were about 0.6, indicating that the soil in these locations likely has some short-term cohesion to maintain the steep slopes. During large earthquakes, these materials can be expected to be displaced down-slope.

- At Cross-section C-C', where historic fill lies between Battery Boutelle and the top of the bluff, the face of the fill at the top of the bluff is marginally stable under static conditions based on a calculated factor of safety of 0.62, indicating some cohesion may be present in the soil. During a large earthquake, the face of the fill could move down-slope and away from the buried front wall of the Battery Boutelle. Battery Boutelle, although only about 40 feet from the top of the slope face (beyond the battery's frontal apron), is not likely to be significantly at risk because it is believed to be founded on serpentinite bedrock which is relatively strong at the bluff top.

- At Cross-section F-F', where historic fill lies between Battery Marcus Miller and the top of the bluff, the face of the fill at the top of the bluff is marginally stable under static conditions based on a calculated factor of safety of 1.04. During a large earthquake, the face of the fill could move down-slope. However, this movement would not likely affect Battery Marcus Miller because it is located about 100 feet from the top of the slope face (beyond the battery's frontal apron).

Conditions during and after Waste fill Removal

- Where removal of the waste fill will expose mélange or serpentinite (Cross-section A-A'), the exposed bedrock slopes should be stable under static conditions based on calculated factors of safety of at least 2. In the long-term, the risk of bedrock slope movements during a large earthquake based on these factors of safety calculations is small.

- Where removal of waste fill will expose sloping layers of historic fills, landslide deposits or native soils (Cross-sections C-C' and H-H'), these soils could be unstable and subject to sliding based on calculated factors of safety ranging from 0.53 to 1.1. In the long-term, the risk of slope movements in these exposed soils during a large earthquake is likely to be large based on these relatively low calculated factors of safety.

- Analyses of equipment and stockpile loads at the tops of the slopes indicate that setbacks on the order of 10 feet from the slope face will generally be sufficient based on calculated factors of safety greater than 1.3. Soils at the top of the bluff remaining after Phase 1 waste removal will be relatively thin (or absent) and underlain by relatively strong serpentinite bedrock.

- For the cross-sections analyzed, none of the areas of planned waste fill removal in BBDA-1 will affect the existing conditions at either Batteries Boutelle or Marcus Miller. In the area between the two Batteries, where waste fill will be removed during Phase 1, the waste fill is relatively shallow and should not impact the stability of the Batteries Boutelle and Marcus Miller, which are believed to be founded on serpentinite bedrock based on evaluation of borings drilled along the bluff top adjacent to the batteries.

7.2.2 Baker Beach Disturbed Area 1A

Cross-section G-G' is located within BBDA-1A (Figure 2) and is shown on Figure 6. Stability analyses of this section indicate the following:

Existing Conditions

- The existing relatively gentle slopes of the historic and waste fills in BBDA-1A at the top of the bluff near Battery Marcus Miller can be considered stable under static conditions based on calculated factors of safety equal to or greater than 1.43. During a strong earthquake, down-slope movements towards the bluff face could occur.

- Battery Marcus Miller lies approximately 90 feet from the top of the slope face (beyond the battery's frontal apron) at BBDA-1A. Battery Marcus Miller is believed to be founded on serpentinite, so it is not likely to move down slope.

Conditions during and after Waste Fill Removal

- Removal is not likely to cause stability problems for the exposed underlying native soils, which are relatively flat lying in BBDA-1A, because the waste fill is at the top of the bluff.

- Waste fill removal may require excavation of some historic fill that is adjacent to and partially surrounded by the waste fill (historic fill is considered an historic resource). However, it is not expected that enough historic fill would be removed on the battery apron that would result in steep excavation slopes.

7.2.3 Baker Beach Disturbed Area 2

Cross-section E-E' is located within BBDA-2 (Figure 2) and is shown on Figure 7. Stability analyses of this section indicate the following:

Existing Conditions

- The existing relatively gentle slopes of the historic and waste fills in BBDA-2 at the top of the bluff south of Battery Godfrey can be considered stable under static conditions based on calculated factors of safety equal to or greater than 1.46. During a strong earthquake, down-slope movements towards the bluff face could occur.

Conditions during and after Waste Fill Removal

- After removal of the waste fill and any overlying historic fill, the exposed slopes in the underlying historic fill and native soils should be stable under static conditions based on a calculated factor of safety equal to or greater than 1.40. During a strong earthquake, the steepest slope in the exposed historic fill could move laterally.

7.2.4 Baker Beach Disturbed Area 2A

Cross-sections B-B' and D'D' are located within BBDA-2A (Figure 2) and are shown on Figure 8. Stability analyses of these sections indicate the following:

Existing Conditions

- The waste fill and other fill on the steep bluff slopes at BBDA-2A can be considered unstable to marginally stable in their existing condition based on calculated factors of safety as low as 0.52. This low factor of safety indicates that the fill materials have some cohesion to maintain their relatively steep slopes. During a strong earthquake, large movements of these fills, could occur.

- The steep slope face of the thin layer of historic fill on top of the bluff is also marginally stable in its current condition. Historic fill near the slope could move laterally during a strong earthquake. However, this lateral movement of historic fill is not likely to affect Battery Godfrey because it is located at least 75 feet from the top of the slope face and is believed to be founded on serpentinite based on evaluation of borings drilled on the bluff top near the batteries.

Conditions during and after Waste Fill Removal

- Removal of the waste fill from the steep bluff slopes will expose sloping layers of disturbed historic fill and native soils. These exposed slopes could be unstable and subject to sliding based on low calculated factors of safety ranging from 0.62 to 0.83. Based on these calculations, there is a long-term risk of downslope movements in these exposed soils during a large earthquake.

- The waste fill on the steep bluff slopes is separated from the historic fill at the top of the bluff by outcropping serpentinite bedrock. Thus, the waste fill removal will not affect the stability of the historic fill at the top of the bluff, nor Battery Godfrey located at least 75 feet from the slope face.

- Analyses of equipment and stockpile loads at the tops of the bluff slopes (Cross-section D-D') indicate that setbacks on the order of 10 feet from the slope face will generally be sufficient based on calculated factors of safety greater than 1.3. The historic fill and native soils at the top of the bluff are relatively thin and underlain by serpentinite bedrock at this location.

7.3 Other Considerations for Slope Stability during Construction

The marginal stability of the fill, landslide deposits and native soils on the steep bluff slopes at BBDA-1 and BBDA-2A (based on observations and calculated factors of safety) indicate that excavation of waste fill could trigger movements of slopes above the excavation areas (unless the upper areas are exposed bedrock). Most soil layers are relatively thin, so the depth of slope movement is likely to be limited to top of the underlying bedrock. However, the lateral extent of soil movement from up the hill is difficult to quantify based on current methods of analyses of lateral movement.

In BBDA-1, groundwater seeps indicate that groundwater is relatively shallow or at the ground surface in portions of this waste fill area. With shallow groundwater and loose fill soils, there is a risk that construction excavations and equipment vibrations may induce liquefaction and localized soil debris flows – as occurred during the excavation of Test Pit BB1TP102 in this area.

7.4 Considerations for Long-Term Slope Stability

The stability analyses performed for this investigation do not specifically address the potential for long-term instability of the steep bluff slopes that could result from natural processes (other than earthquakes), such as weathering, rainfall runoff and erosion, burrowing by animals, and attack at the base of the bluffs by ocean storm or tsunami waves. After waste fill removal, the remaining fills, landslide deposits and native soils that thinly blanket portions of the bluff slopes will be most susceptible to down-slope movements over time. However, even the mélange and serpentinite bedrock will be at risk of erosion,

landslides and rockfalls, as evident from the existing condition of the bluff slopes near the waste fill areas. There will be increased risk of surface erosion of the slopes immediately following waste removal until native vegetation has been re-established.

8.0 CONCLUSIONS AND RECOMMENDATIONS

This section summarizes results of the field investigation and proposes recommendations if excavation is selected as the remedy for the BBDAs; it is divided into three primary sections. Section 8.1 summarizes environmental investigation results with respect to evaluation of current and previous data and describes how the project objectives (previously referred to as "data gaps") were met. Section 8.2 summarizes geotechnical/structural evaluations and makes recommendations during implementation of an excavation remedy. Section 8.3 recommends treatment methods to protect historical and cultural resources during and after implementation of an excavation remedy.

8.1 Environmental Investigation Results

The field investigations have confirmed the presence of COCs in the four BBDAs. In general, evaluation of recent and previous analytical results suggests that the source of contamination is waste fill (afw), and contaminated soil is primarily located within the mapped footprint of the waste fill. Contamination found in other types of materials such as bedrock (KJm, KJss and KJsh, Sp), historic fill (afh, afh1, afh2), and native soils (Qls, Qcol, and Qb) was detected in cases where those materials were in close proximity to or in contact with waste fill. Although few samples have been collected for chemical analysis from areas outside of the limits of waste fill, based on the relative low mobility of contaminants found, contamination is not expected to extend far beyond the mapped limits of the waste fill.

Based on investigations conducted to date, it appears that waste fill and underlying and/or adjacent historic fill at BBDAs -1, -1A, -2, and -2A contain COCs above cleanup levels and require remediation. At BBDA-1, undisturbed historic fill associated with Batteries Boutelle and Marcus Miller and buried cultural resources may contain COCs above cleanup levels where in contact with waste fill. At BBDA-2, undisturbed historic fill contains COCs above cleanup levels in the vicinity of a former metals recycling and disposal area. In the frontal slopes of the batteries at BBDAs -1 and -2A, shallow, undisturbed historic fill is contaminated with PAHs probably from fragments of asphalt/tar roofing material derived from the adjacent batteries. The historic fill in these areas that were contaminated by waste fill and shallow soil on the frontal slopes containing asphalt/tar roofing material fragments will likely require remediation.

The following sections describe area-specific conditions with respect to evaluation of environmental and cultural resource studies, and present how data gaps identified by DTSC in their preliminary review of the RAP sections on the BBDAs were met.

8.1.1 Area-Specific Conditions

Although each BBDA contains waste fill with COCs above action levels, the landfills represent different episodes of waste disposal and have differing site conditions that are important to incorporate in their remedial design. The following describes each of the BBDAs and other significant fill areas and fill materials:

> **BBDA-1 –** Dumping of waste materials (refuse and construction debris) downslope may have began around World War I. Waste disposal activities began with direct downslope dumping of debris and refuse generated possibly from the barracks to the east. Two incinerators were constructed in 1922 and 1934, and dumping continued throughout the incinerator operation until around 1967. Foundation materials of what is believed to be the former incinerator was encountered during trenching. Waste disposal activities continued in the area between Batteries

Boutelle and Marcus Miller, eventually covering four former mortar platforms and the adjacent opening to Magazine 21 with refuse and construction debris.

Waste fill is thickest in the center of the slope face, estimated to be greater than 20 feet thick based on a test pit excavated to that depth. Test pits indicate that the waste fill is about 8 feet thick at the bottom of the slope face below the seep, and about 10 feet thick on the bluff top. Groundwater measurements in piezometers indicate that about 6 feet of the waste is saturated at the bottom of the slope.

Waste fill is in contact with historic fill that comprise Batteries Boutelle and Marcus Miller earthworks, and waste fill is above the chert fill that covers buried mortar platforms in the area. This layer of chert fill may serve as a marker unit for the location of the historic fill when the removal of waste in this area takes place. Based on sampling conducting as part of this investigation, it is likely that there will be some removal of historic fill that was contaminated by the waste fill in the area of the frontal slope where the incinerator was located. At locations on the frontal slopes where fragments of asphalt/tar roofing material are present at the ground surface, shallow soil will also need to be removed because sampling has shown that PAHs [e.g., benzo(a)pyrene at 0.037 mg/kg] exceed cleanup levels (0.027 mg/kg) in surface soil.

BBDA-1A – This waste is primarily roofing material, from the roof of Battery Marcus Miller (remnants of similar roofing material are visible on the battery roof). Waste fill is thin (less than 2 feet thick), is unsaturated, and is in contact with the battery's historic fill frontal slope. Waste removal will likely require removal of some of this historic fill that is in contact with waste fill.

BBDA- 2 – Waste fill was placed on a cut surface that removed portions of the earthworks related to West Battery and Endicott Period fortifications. This waste, primarily construction and landscaping debris with some household refuse, was probably dumped during and after construction of the Battery Godfrey parking lot in 1954. The waste is generally less than 10 feet thick, is unsaturated (though perched conditions may exist during the wet season), and diminishes in thickness with distance from the cliff edge. Bluff-top historic fill (afh1) displaced during battery construction that is in contact with waste fill will likely require removal.

BBDA-2A – Parking lot construction west of Battery Godfrey began in 1954, and it appears that part of the frontal slope of the battery (mapped as afh2) was pushed downslope. The parking area may have been used to provide better access to the former dump and recycling areas to the south. This displaced historic fill is overlain by waste debris (primarily metal and construction debris with some household refuse), dating the disposal of the waste fill after 1954. Layers of brick were encountered beneath the waste fill that may represent episodic disposal of battery materials related to demolition of structures.

The waste fill material varies widely in thickness, but is greater than 14 feet thick in the southern portion of BBDA-2A, decreasing in thickness to the north. Saturated conditions were noted in test pits at 8 to 10 feet bgs, and a natural seep exists near the toe of the slope. Removal of waste material will likely require removal of the displaced fill beneath it that is in contact with the waste fill. At locations on the frontal slopes where fragments of asphalt/tar roofing material are present at the ground surface, shallow soil will also need to be removed because sampling has shown that PAHs and selenium, vanadium, and zinc are present in shallow soil at concentrations (0.34 [for benzo(a)pyrene], 0.58, 75, and 190 mg/kg, respectively) that exceed cleanup levels of 0.027, 0.5, 74, and 160 mg/kg, respectively.

Fill Area West of Merchant Road – This fill material (afo1 and afw) may have had several sources. The area west of Merchant Road was used as a dumping location to relocate materials

from battery demolition or construction of the Golden Gate Bridge. Filling of this area was also noted in a 1967 photograph. This fill may be associated with the similar time period for construction of Presidio Letterman Hospital.

The fill is estimated to be between 2 and 7 feet thick. Borings encountered bedrock at 7 to 10 feet bgs. No saturated conditions were encountered. Geologic mapping and observations made when excavating test pits indicate that there is an area of waste fill (afw) just east of the Covered Way that contains tar-cemented gravels, concrete, wood, charcoal, and auto parts. Soil samples collected from a test pit excavated in this area shows only arsenic above cleanup levels for serpentinite soil, but not for Colma formation soil. Because this waste fill contains material (tar-cemented gravels, auto parts), that likely contain chemicals of concern above cleanup levels, it is recommended that this waste soil be removed.

Other fill (afo1) was encountered in trenches excavated in the central and southern portions of the site. Debris in the fill included concrete, brick, asphalt, and wood. Samples collected from trenches excavated in this area shows only arsenic concentrations (5.8 mg/kg) above cleanup levels for serpentinite soil (5.4 mg/kg), but not Colma formation soil (6.2 mg/kg). Because this waste fill contains only construction-type debris and does not contain chemicals above cleanup levels, no remediation is recommended for soil in the southern and central portions of the site.

Displaced Historic Fill – Historic fill was displaced downslope as a result of demolition of West Battery fortifications; this fill may have been used in the construction of Endicott Batteries. Historic fill (afh) was placed against Endicott Batteries to serve as an apron to protect the batteries during an assault. Older displaced historic fill (afh1) may have been derived from West Batteries and may have been pushed downslope to make room for the newer batteries (e.g., the presence of afh1 mapped downslope from Batteries Godfrey and Marcus Miller). Displaced historic fill (afh2) may have been originally part of the Endicott Batteries, but was pushed downslope during construction of Battery Godfrey parking lot.

It may be beneficial to salvage some of the displaced historic fill (afh2) during remedial activities for use to repair areas where historic fill is removed as part of the remediation.

8.1.2 Data Gap Results

As discussed in Section 2.2.3, the objectives of the Environmental FSP were to address several data gaps identified by DTSC in their preliminary review of the RAP. Table 17 presents a summary of sampling locations and frequency during this study. The following summarizes findings from the environmental sampling investigation and evaluates how the data objectives were met.

8.1.2.1 Historic Fill Contamination (Data Gap 1)

The presence and concentrations of contaminants in historic fill (earthworks) surrounding historic batteries was characterized by collecting 12 soil samples from historic fill encountered in the cultural resource trenches. Samples were collected near Battery Godfrey from Trench 2 at depths of 1, 11.5, and 15 feet; and from Trench 3 at 4, 7, and 10 feet. Between Batteries Boutelle and Marcus Miller, samples were obtained at depths of 2.5, 3.5, 5, 6, and 7 feet (includes a duplicate at 2.5 feet) from Trench 5. Geotechnical samples only were obtained from Trench 4. The sampling frequency met the FSP requirements.

Chemical analyses indicate that displaced historic fill that lies adjacent to or underlies waste fill in these areas contains COCs (arsenic at 6.6 mg/kg, benzo(a)pyrene at 0.037 mg/kg, 4,4’ DDT at 0.052 mg/kg,

dieldrin at 0.042 mg/kg) above cleanup levels of 5.4, 0.027, 0.0082, and 0.03 mg/kg, respectively, and requires remediation. Based on the relative low mobility of the contaminants found in the fill, contamination is not expected to extend beyond the mapped limits of the fill areas and is not expected to be present above cleanup levels in underlying native soils or bedrock.

8.1.2.2 Bluff Top Fill Contamination (Data Gap 2)

The presence and concentrations of contaminants in fill materials excluding historic fill on the bluff top were evaluated by collecting samples at 0.5 foot from BBSB103, located just west of Battery Marcus Miller and from BB2ASB100 (at 4 feet) located west of Battery Godfrey. Samples were also collected from a boring and test pits excavated in an "Undesignated Area," which was discovered after preparation of the Environmental FSP.

Analytical results show that COCs in soil samples from BB2ASB100 were below cleanup levels, indicating that in place historic fill adjacent to the batteries has not been significantly impacted and will not require remediation. Samples analyzed from BBSB103 (BBDA-1) and BBSB106 (BBDA-2A) show that where asphalt/tar material is present on the frontal slopes of the batteries, shallow soil contains PAHs [benzo(a)pyrene at a maximum concentration of 0.34 mg/kg, benzo(a)anthracene at a maximum concentration of 0.27 mg/kg, benzo(b)fluoranthene at a maximum concentration of 0.28 mg/kg, indeno(1,2,3-cd)pyrene at a maximum concentration of 0.27 mg/kg, and dibenzo(a,h)anthracene at a maximum concentration of 0.13 mg/kg] exceeding cleanup levels of 0.027, 0.27, 0.27, 0.27, and 0.078 mg/kg, respectively, and therefore, will require remediation.

In the Undesignated area, samples were obtained from Boring BBSB119 at 2.5 and 4.5 feet, and from Test Pits BB1TP110, -111, and -113. Sampling in this area shows that the only chemical exceeding cleanup levels for serpentinite soil was arsenic, which was detected at concentrations ranging from 3.2 to 5.8 mg/kg, which exceeded the cleanup level for serpentinite soil (5.4 mg/kg) but not Colma formation soil (6.2 mg/kg). Because the Colma formation is present in this area, these arsenic levels are not considered to represent contamination related to the fill.

8.1.2.3 Incinerator Contaminants (Data Gap 3)

Sampling was conducted to evaluate the presence of ash and contaminants around a former incinerator facility at BBDA-1. A sample was obtained in the southern end of Trench 5 at a depth of 5 feet [BB1TP108(5.0)] and analyzed for TPH, VOCs, PAHs, Title 22 metals, pesticides, PCBs, and dioxins and furans. Metals [arsenic (6.7 mg/kg; cleanup level of 5.4 mg/kg), barium (2,500 mg/kg; cleanup level of 320 mg/kg), cadmium (4.5 mg/kg; cleanup level of 1.9 mg/kg), lead (420 mg/kg; cleanup level of 160 mg/kg), mercury (0.56 mg/kg; cleanup level of 0.4 mg/kg), molybdenum (14 mg/kg; cleanup level of 12 mg/kg), silver (140 mg/kg; cleanup level of 2 mg/kg), zinc (930 mg/kg; cleanup level of 160 mg/kg)], benzo(a)pyrene (0.070 mg/kg; cleanup level of 0.027 mg/kg), TPH fuel oil/motor oil (3,500 mg/kg; cleanup level of 980 mg/kg), and TPH as diesel (780 mg/kg; cleanup level of 700 mg/kg) were detected above cleanup levels and the calculated 2,3,7,8-TCDD toxic equivalency value (TEQ) of 0.00026381 mg/kg for detected dioxins and furans exceeded the RWQCB ESL and EPA Region IX PRG for 2,3,7,8 TCDD. No evidence of incinerator waste was observed in Trench 4 as assumed in the FSP, so the sampling frequency met the minimum requirements stipulated in the FSP. Evidence of additional former incinerator debris was observed at three other locations: Trench E (western edge at 10 feet), Trench BB1TP106 (charcoal), and BB1TP102 (melted glass). Analytical testing of waste fill samples containing incinerator waste or waste soil located down slope and in the vicinity of the incinerator showed elevated levels of PAHs and metals, which would be expected from incinerator waste material as detailed in the table below.

COC	Waste Fill		Cleanup Level
	Maximum Concentrations in mg/kg	No of samples exceeding Cleanup level/No of Samples Analyzed	mg/kg
Arsenic	230	5/15	5.4
Antimony	123	6/14	5
Barium	2500	5/15	320
Cadmium	28	8/15	1.9
Copper	2200	4/15	85
Lead	6000	18/38	160
Silver	140	6/15	2
Selenium	2.2	7/14	0.5
Mercury	7.7	4/15	0.4
Molybdenum	84	2/6	12
Vanadium	110	3/15	74
Zinc	73000	20/35	160
TPH Diesel	780	1/5	
TPHmo	3500	1/5	980
Methylene chloride	0.23	4/13	0.076
DDT	0.39	7/12	0.0082
Dieldrin	0.06	5/12	0.03
Endrin	0.005	1/12	0.004
PCBs	0.43	3/16	0.033
PAHs (benzo(a) pyrene)*	0.33	3/7	0.027
Dioxins and Furans (2,3,7,8-TCDD TEQ)	0.00026388		0.0000045** 0.0000039***

*Other PAHs were detected above cleanup levels. The maximum concentration of benzo(a)pyrene is shown to represent PAH contamination

**RWQCB residential ESL
*** EPA Region IX residential PRG

During remediation, this material will require sampling and handling in accordance in accordance with DTSC guidance for investigation and characterization of Burn Dumps. This will include analyzing selected samples for pH, metals, PCBs, total recoverable hydrocarbons, semi-volatile organic compound (SVOCs), and dioxins and furans. Except for pH, these analytes are COCs for the site and therefore, these analyses will be included in the excavation confirmation and stockpile characterization sampling programs. In addition, to evaluate whether the excavated soil comprises hazardous waste, the following analytical protocols will be followed:

- Metals (former CAM 17 metals) results will be compared to Total Threshold Limit Concentration (TTLC) criteria to assess whether excavated soil represents California only hazardous waste

- Representative samples will be analyzed using the Waste Extraction Test (WET) and compared to Soluble Threshold Limit Concentrations (STLCs) to evaluate whether the excavated soil is California only hazardous waste. DTSC guidance indicates that the WET test be performed for cadmium, trivalent chromium, hexavalent chromium, nickel, lead, and zinc on three samples that exhibit the

highest lead concentrations. In addition to these analyses, any samples that have a total metal result that exceeds ten times the STLC criteria should also be analyzed using WET.

- Analyze samples from excavated soil that have the highest lead concentration for silver, arsenic, barium, cadmium, chromium, mercury, lead, and selenium using the Toxicity Characteristic Leaching Procedure (TCLP) and compare results to Resource Conservation and Recovery Act (RCRA) toxicity characteristic to assess whether the soil is a RCRA hazardous waste.

- Analyze selected samples that show the highest lead concentration using the Deionized Water (DI) WET for lead and compare results to DI WET criteria to evaluate if there is potential for leaching to groundwater.

8.1.2.4 Southeast BBDA-2 Contamination (Data Gap 4)

Samples were collected at the surface and at 2 feet bgs from Boring BB2SB102 to further evaluate the lateral extent of contamination at the southern limits of BBDA-2. Analytical results show that PAHs (benzo(a)pyrene) are present at concentrations exceeding cleanup levels in surface (0.14 mg/kg) and 2 ft (0.084 mg/kg) soil samples collected from this area (cleanup level is 0.027 mg/kg). No other COCs were detected above cleanup levels. The absence of metals contamination in the soil samples collected from this boring indicates that the samples were likely collected at the perimeter of the area impacted by waste fill.

8.1.2.5 Salvage/Recycling Facility Contaminants (Data Gap 5)

South of BBDA-2, sampling and analysis was performed to evaluate the presence of contaminants around a former salvage/recycling facility. Surface and shallow (2 feet bgs) samples were obtained from two hand augered soil borings located at the salvage shop (BBSB108) and dump area (BBSB109). This met the FSP required sampling frequency. Analytical results show that arsenic (maximum concentration of 10 mg/kg; cleanup level of 5.4 mg/kg), lead (maximum concentration of 1,900 mg/kg; cleanup level of 160 mg/kg), mercury (maximum concentration of 1.1 mg/kg; cleanup level of 0.4 mg/kg), and zinc (maximum concentration of 250 mg/kg; cleanup level of 160 mg/kg) indicate that past practices related to metals recycling and disposal have impacted shallow soil in this area. Undisturbed historical fill in the vicinity of the former metals recycling and disposal area contains metals and PAHs above cleanup levels and requires remediation. Analytical results for samples from BBSB108 and BBSB109 indicate that contamination may extend to at least 2 feet bgs in this area (arsenic at 6.8 mg/kg, lead at 180 mg/kg, mercury at 1.1 mg/kg, and zinc at 250 mg/kg). Although no perimeter samples have been collected to characterize the areal extent of contamination in this area, it is expected that contamination will be limited to the general area where metals disposal and recycling operations were performed.

8.1.2.6 BBDA-1, and 2A Seep Water Contaminants (Data Gap 6)

Several seep water samples were obtained from two piezometers constructed at BBDA-1 in the seep zone section as well as from a seep located at the base of BBDA-2A. Although the FSP indicated that surface water samples would be collected from the BBDA-1 seep, these samples were obtained from the casing of piezometers BB1PZ101 and BB1PZ100 after development. Three rounds of samples were collected from these two piezometers. The first two rounds of sampling included only BB1PZ101. The first round of samples from BB1PZ101 were analyzed for VOCs, PAHs, dioxins and furans, TPH as gasoline, diesel, and motor/fuel oil, pesticides, PCBs, and dissolved metals. The second round of samples from BB1PZ101 was analyzed for dissolved Title 22 metals (field filtered sample) and total Title 22 metals (unfiltered sample). The third round of samples collected from BB1PZ101, BB1PZ100, and BB2ASW100 (BBDA-2A) was analyzed for VOCs, PAHs, TPH as gasoline, diesel, and motor/fuel oil,

pesticides, PCBs, dissolved Title 22 metals (field filtered sample) and total Title 22 metals (unfiltered sample). Analytical results were compared to the most stringent of surface, fresh, and drinking water cleanup levels presented in RWQCB, 2004 and EKI, 2002. The only samples showing exceedances of cleanup levels are those that were collected in the second and third round of sampling. In the second round, the unfiltered sample contained arsenic, copper, and lead at concentrations exceeding cleanup levels in the unfiltered but not the filtered water samples. Because the cleanup levels for these metals are based on dissolved concentrations, these levels are not considered applicable to unfiltered samples. The results of the third round of sampling show TPH motor/fuel oil (C24-C36), chrysene, antimony, arsenic, cadmium, chromium, copper, lead, mercury, nickel, selenium, and zinc at concentrations exceeding cleanup levels. Only unfiltered samples exceeded cleanup levels for arsenic, cadmium, chromium, lead, nickel, and zinc and those cleanup levels are based on dissolved metals concentrations and are therefore not applicable to unfiltered samples. The sample collected from the piezometer screened in native soil contained the highest concentrations of TPH. Based on the results of the February 2006 sampling, there are elevated levels of contaminants TPH motor/fuel oil (at a maximum concentration of 3,100 µg/L; cleanup level of 3,100 µg/L), mercury (at a maximum concentration of 11 µg/L; cleanup level of 0.025 µg/L), and selenium (maximum concentration of 5.5 µg/L; cleanup level of 5 µg/L) in the seep water. These results indicate that COC concentrations in the seep water may pose risks to human or ecological receptors. In addition, because several compounds exceed surface water cleanup levels, water drained from the slopes prior to remediation may need to be contained and pumped up the slope for proper disposal unless a National Pollutant Discharge Elimination System (NPDES) permit can be obtained to dispose of the water onto the beach.

8.1.2.7 Beach Waste Debris Contaminants (Data Gap 7)

Three selected samples of beach sand directed adjacent to waste debris were obtained at depths of 0.5 feet at BBDA-1 (BB1SB113 and -114) and BBDA-2A (BB2ASB112). This met the FSP required sampling frequency. Analyses of these samples show cleanup level exceedances for methylene chloride in samples collected at BBDA-1 (BB1SB114 contained methylene chlorine at 0.12 mg/kg, which exceeded the cleanup level of 0.076 mg/kg). These results are considered suspect because:

- Methylene chloride is a common laboratory contaminant.
- No other COCs were detected above cleanup levels.
- It is highly unlikely that methylene chloride would be present at elevated concentrations in sand impacted by wave and tidal action.

The sample collected from the beach at BBDA-2A contained only one COC, arsenic, at a concentration (6.4 mg/kg) exceeding the cleanup level of 5.9 mg/kg which represents background for Beach Dune sand. Because the background dataset may not represent the range of metals concentrations present in recent beach deposits, this exceedance may not represent contamination from past site-disposal practices. Because methylene chloride results are suspect and the arsenic is unlikely to represent contamination related to site disposal practices, remediation of the beach sand is not necessary. However, as part of the planned remediation, debris on the beach will be removed because it is related to the waste fill that will be removed on the slopes.

8.1.2.8 Confirmation Non-Waste Fill Soil Sample Contaminants (Additional Samples)

The presence and concentrations of contaminants in non-fill materials were further evaluated by collecting samples from three locations at BBDA 1, 2A, and 2 as described below:

- BBDA 1 - Samples were collected at BB1SB115 (0.5 and 1.0 ft) to verify metals concentrations previously detected in RI Boring BBSB05 (arsenic at 11.3 mg/kg compared to a cleanup level of 5.4 mg/kg, antimony at 100 mg/kg compared to a cleanup level of 5 mg/kg, selenium at 2.37 mg/kg compared to a cleanup level of 0.5 mg/kg, silver at 2.63 mg/kg compared to a cleanup level of 2 mg/kg, and vanadium at 99.4 mg/kg compared to a cleanup level of 74 mg/kg) which was mapped as native soil/colluvium in an area downslope of BBDA-1 waste fill. Analytical results from BB1SB115 confirmed the presence of metals (arsenic at a maximum concentration of 14 mg/kg compared to a cleanup level of 5.4 mg/kg, copper at a maximum concentration of 130 mg/kg compared to a cleanup level of 85 mg/kg, selenium at a maximum concentration of 1.2 mg/kg compared to a cleanup level of 0.5 mg/kg, and zinc at a maximum concentration of 370 mg/kg compared to a cleanup level of 160 mg/kg) in this area, indicating that native soil downslope of the waste fill has been impacted by past site disposal practices.

- BBDA 2A - One sample was collected from 1.0 foot bgs from BBSB120 which was located adjacent to BBSB106 where PAHs (e.g., benzo(a)pyrene at 0.34 mg/kg; cleanup level 0.027 mg/kg), and zinc (190 mg/kg; cleanup level of 160 mg/kg) had been detected above cleanup levels in a sample collected at 0.5 foot bgs. Analytical results for BBSB120 show selenium (0.58 mg/kg; cleanup level of 0.5 mg/kg) and vanadium (75 mg/kg; cleanup level of 74 mg/kg) just above cleanup levels. PAH results were not detected or reported at concentrations below cleanup levels. It is noted that results for benzo(a)pyrene were qualified as not detected at a reporting limit of 0.064 mg/kg which exceeded the cleanup level of 0.027 mg/kg. Therefore the presence or absence of benzo(a)pyrene below cleanup levels at 1 ft bgs cannot be confirmed. During sampling, fragments of asphalt/tar roofing material were observed in the area which were the likely source of the PAHs detected in the soil sample collected at BBSB106. Results of the sampling suggest that the contamination in this area is shallow as the zinc and PAHs were below cleanup levels in the 1.0 foot sample and zinc and selenium concentrations were close to cleanup levels.

- BBDA 2 - Samples were collected at depths of 0.5 and 1.0 ft from BB2SB110 to confirm previously detected concentrations of cadmium (2.2 mg/kg compared to a cleanup level of 1.9 mg/kg) and selenium (1.29 mg/kg compared to a cleanup level of 0.5 mg/kg) in RI boring BBSB07. These samples were collected from areas mapped as native soil/colluvium. Analytical results for the samples from BB2SB110 confirm that selenium (1.3 mg/kg) is present above cleanup levels in this area but do not confirm the previously reported cadmium concentrations (cadmium was detected at an estimated maximum concentration of 0.32 mg/kg) and therefore cadmium concentrations in this area are not considered to pose risk. Selenium concentrations are not believed to be related to site contaminants, because other metals (other than cadmium which was not confirmed) are not present above cleanup levels in this area. It is possible that the selenium levels do not represent site contamination because there may be local variations in native metals concentrations that are not captured by the background metals dataset.

8.1.2.9 Magazine 21 Sampling

As discussed in the FSP dated March 14, 2005, sampling of the interior of Magazine 21 for contaminants related to arms or ordnance formerly stored in the magazine is planned to be addressed under a separate FSP and investigation.

8.2 Geotechnical/Structural Evaluation Results

The geotechnical study evaluated information from borings, test pits, trenches, and surface geophysical and geologic mapping to assess slope stability conditions. It should be recognized that these data are

most accurate at the respective investigations points and that interpolation between the points results in a lesser degree of confidence for these intermediate areas.

A significant finding from the trenching investigation was the identification of a pervasive chert fill as observed in cultural resource trenches at BBDAs-1 and -2. This layer may be provide a marker for the base of the waste fill during removal.

The battery structural evaluation did not identify structural instability. Structural cracks at Battery Boutelle may be the result of consolidation of backfill material beneath the battery apron, or movement of the soil mass west of the parapet wall towards the coastal bluff top. Proposed remediation and construction activities should not adversely affect the structural integrity of the fortifications. However, it is recommended that a battery structural monitoring program be implemented during waste removal. This will provide data that can be used to determine the need for ground improvement (especially near Battery Boutelle) during construction or post remediation.

One significant finding of the structural evaluation was the determination that it is possible to remove material from BBDA-1A across the top of Battery Marcus Miller, provided that specific shoring measures are used.

Slope stability (both during and after remedial activities) was the primary geotechnical concern evaluated during the geotechnical study. Soil and bedrock materials in the Baker Beach bluff areas are susceptible to erosion, downslope movements, and landslides as a result of natural processes. Evaluation of short-term slope stability was performed based on collection and analyses of field samples from borings and test pits, mapping of geologic units and observations made regarding current site conditions, and performing slope stability modeling to calculate factors of safety. Based on slope stability analysis, the removal of the waste fill is feasible, provided that geotechnical recommendations presented below are incorporated into the remedial design.

Excavations required for the waste fill removal actions could increase the risk of slope instability affecting significant resources (such as historic fill and batteries). These increased risks can be reduced by dewatering of areas to be excavated, locating temporary stockpiles and equipment staging areas at least 10 back from the slope face, sequencing the waste removal from the top of slope to the bottom of the slope, selecting temporary fill and cut slope inclinations that are stable in the short term, and selecting finished slope inclinations that are at least as stable as the current natural bluff slopes.

As mentioned in Section 2.2.2, the specific Geotechnical FSP objectives were to obtain data to: (1) assess how the selected remedial action could affect the stability of historical gun battery emplacements at the site; (2) evaluate the stability of areas identified for use and staging of heavy equipment required to perform the remedial work; and (3) evaluate the stability of the debris areas that will be removed as part of the selected remedial action. The following sections discuss these three objectives with respect to short-term slope stability during and after waste fill removal as well as recommended mitigation measures during construction and post-remediation to reduce the risk of slope instability.

8.2.1 Battery Stability

The results of slope stability analyses described in Section 7.0 indicate that planned excavations of waste materials will not likely have adverse impacts on the stability of the batteries because it is believed that the battery foundations are underlain by serpentinite bedrock that is relatively strong at outcrops near the top of the bluffs and the batteries are setback between 40 and 90 feet from the slope face. The following discusses each disposal area with respect to waste disposal and battery stability:

BBDA-1 – Removal of waste fill in BBDA-1 will not likely affect the existing conditions at Batteries Boutelle and Marcus Miller. In the area between the two Batteries, the waste fill is relatively shallow and should not impact the stability of these batteries because they are believed to be founded on relatively strong serpentinite bedrock material that is relatively strong at the top of the bluffs. Where removal of waste fill will expose sloping layers of historic fill, it is not known whether these soils could be unstable and subject to sliding. In the long-term, the risk of slope movements in these exposed soils during a large earthquake is likely to be large.

BBDA-1A - Because the waste fill in BBDA-1A is located on a relatively flat-lying area at the top of the bluff, removal is not likely to cause stability problems for the exposed underlying native soils. Waste material is very shallow and of a relatively small quantity (200 to 400 cubic yards), but is located on the battery frontal apron. As a result waste fill removal may require the excavation of some historic fill that is adjacent to and partially surrounded by the waste fill. Historic fill is considered a protected resource, so this would need to be performed under the close supervision of cultural specialists. Removal of the waste and small quantity of historic fill is not expected to steepen excavation slopes to the point where they would become a stability problem.

BBDA-2 - After removal of the waste fill in BBDA-2 and any adjacent disturbed contaminated historic fill, the exposed slopes in the underlying historic fill and native soils should be stable under static conditions.

BBDA-2A – Waste fill in BBDA-2A is on a steep bluff slope that is separated from the historic fill at the top of the bluff by an outcrop of serpentinite bedrock, which is considered a relatively strong material based on factor of safety calculations and material property testing. As a result, waste fill removal below the serpentinite bedrock is not expected to affect either the stability of the historic fill at the top of the bluff or Battery Godfrey, which is located about 75 feet from the slope face.

8.2.2 Stockpiles and Staging of Heavy Equipment

Potential areas for stockpiling soil and staging heavy equipment include the area between Battery Boutelle and Marcus Miller (part of BBDA-1) and the parking lot west of Battery Godfrey (above BBDA-2A). Both of these locations are relatively flat but are near steep breaks along the slope face, requiring an evaluation of the effect on slope stability of temporary loading near the slope. The results of slope stability analyses described in Section 7.0 indicate that setbacks on the order of 10 feet from the slope face will generally be sufficient.

8.2.3 Debris (Disturbed) Area Stability

The stability of debris areas during and immediately after waste fill removal is contingent on how waste removal is sequenced, whether waste fill is dewatered prior to excavation, the inclination of temporary slopes and the properties of the materials being removed, and what soils and bedrock will remain in place after excavation activities have been completed. These issues will be discussed in detail in the following sections.

The following discusses slope stability after the waste fill has been removed:

BBDA-1 - Where removal of the waste fill will expose mélange or serpentinite (Cross-section A-A'), the exposed bedrock slopes should be stable under static conditions. The risk of bedrock slope movements during a large earthquake is considered small. Where removal of waste fill will expose sloping layers of historic fills, landslide deposits or native soils (Cross-sections C-C' and H-H'), these soils could be unstable and subject to sliding based on low calculated factors of safety. These steep

areas are considered to have a high and increased (compared to existing conditions) potential for downslope movement of the exposed soils during a large earthquake.

BBDA-1A - Because the waste fill is at the top of a relatively flat portion of the bluff removal is not likely to cause stability problems for the exposed underlying native soils, which are relatively flat lying. The risk of downslope movement to the exposed soils during a large earthquake is relatively low for both existing conditions and after waste fill removal.

BBDA-2 - After removal of the waste fill and any overlying historic fill, the exposed slopes in the underlying historic fill and native soils should be stable under static conditions. Because the waste fill is at the top of a relatively flat portion of the bluff, these exposed slopes are considered to have a relatively low risk of movement downslope during a large earthquake.

BBDA-2A - Removal of the waste fill from the steep bluff slopes will expose sloping layers of disturbed historic fill and native soils (Cross sections B-B' and D-D'). These exposed slopes could be unstable and subject to sliding based on low calculated factors of safety. These steep areas are considered to have a high and increased (compared to existing conditions) potential for downslope movement of the exposed soils during a large earthquake.

8.2.4 Stability Mitigation Measures During and Post Construction

8.2.4.1 Sequencing Waste Removal

It is recommended that removal of waste fill on the bluff slope face proceeds from the top down as a way to minimize the likelihood of slope instability during remediation. This is particularly pertinent in BBDA-1 and BBDA-2A, which contain very thick deposits of waste fill along the slope face.

8.2.4.2 Engineered Structures

It is recommended that installation and maintenance of rock fall restraint systems below waste fill removal areas on the slopes (i.e., berms, mesh, or fencing) be used until vegetation on the slopes can be reestablished to protect the public from localized rock falls. This would especially be necessary if waste fill is removed from steep slopes that are composed of serpentinite or mélange bedrock. Rock falls are part of a naturally occurring process that usually results in an accumulation of debris on relatively flat slopes, in areas of thick vegetation, or at the bottom of the slope on the beach. After removing waste fill down to a steep, hard substrate, subsequent rock fall debris could move further down the slope and come to rest on the beach and create a possible risk to people on the beach below the construction area.

8.2.4.3 Dewatering

Groundwater was observed near ground surface in BBDA-1 and BBDA-2A, with saturated soils to depths greater than 6 feet in some of the waste fill areas. Data from standpipe piezometers indicate that groundwater levels are well above the expected depths of excavation in the slope areas of BBDA-1. Because of the uncertainty in seepage rates and groundwater conditions, and the large impact they could have on components of the design, it is important that groundwater conditions be considered in the remedial design. It will be necessary to abandon existing groundwater piezometers that could interfere with the removal of waste fill from slope faces prior to the start of Phase I.

The groundwater flow regime at the BBDA-1 "Seep Area" is complex and characterized by a combination of fracture flow through the bedrock and seasonal flows through overlying fill soils. The seepage or flow rates into the remedial excavations will be governed by factors such as groundwater

levels, permeability of overburden soils, the nature and frequency of rock fractures, rock type, and degree of weathering. Water levels could be lower or higher than the historical levels measured in the piezometers. It is very possible that seepage flow will inhibit progress during the excavations, limit the haulage of fill materials if they are saturated, and could require control measures to limit turbid flows onto Baker Beach.

It is recommended that waste fill be dewatered at least one month prior to the start of excavation activities based on the low calculated factor of safety and the small slope failure that occurred during the field investigation below the seep area at BBDA-1.

In addition, the remedial design should require temporary dewatering systems to keep water out of the excavation during remediation. A properly designed, installed, and operated dewatering system should:

- Lower the water levels inside the excavation and intercept seepage from the sides or bottom of the excavation;
- Improve the stability of the excavation and prevent disturbance to the bottom of the excavation; and
- Provide for collection and removal of surface water and rainfall.

Possible methods to control seepage into the excavation include a system of trenches, piping, sumps, and pumps. Use of a flexible portable system is preferable as it allows for sumps to be moved to where seepage is greater than expected and relocated from drier portions of the excavation when they are not necessary.

Based on analytical results from samples collected of the seep water, it may be necessary obtain a NPDES permit to discharge water onto the beach. Retention basins at the base of BBDA-1 or BBDA-2A may be necessary to collect runoff and allow suspended solids to settle if water is discharged onto Baker Beach. If water cannot be directly discharged to the beach, collected water from dewatering wells, sumps, cutoff trenches, or retention basins would require storage and pumping to storage tanks on top of the bluff for eventual disposal.

Long-term water storage in unlined retention basins should be discouraged to reduce infiltration into weak mélange bedrock, which could lead to potential slope failures. Basins with temporary impervious liners could be constructed at the toe of the slope in BBDA-1 and BBDA-2A to increase storage capacity without significant risk of infiltration. If groundwater is encountered at the toe of the slope during basin construction, the lowest point of the basin should be at least 1 foot above groundwater elevation. If the groundwater level is high, it could be necessary to construct wider and shallower basins to achieve the required holding capacity.

8.2.4.4 Retention Basins

Retention basins below the waste fill removal areas may be required to collect sediment until vegetation on the slopes can be reestablished to reduce surface soil erosion from the slopes. This will depend on the material properties of the exposed soil or bedrock after waste debris has been removed.

8.2.4.5 Removal Methods

Remediation earthwork will require grading of various materials consisting fine and coarse-grained soils, rock fragments, refuse ranging in size from broken glass to telephone poles to concrete slabs. Grading operations will be on slopes ranging from near level to vertical. At BBDAs-1 and -2A, excavations for

waste fill will encounter weaker mélange bedrock much deeper with more landslide debris and soil than the other BBDAs.

Excavations to remove waste fill may expose adjacent historic fill. The excavation sidewalls may need to be laid back or partially buttressed to prevent sloughing. Erosion control material may need to be placed on the historic fill to prevent disturbance after remediation.

Several waste removal methods have been evaluated, including use of conventional track excavator and dozer operations to more elaborate schemes involving high-line cable waste fill retrieval, helicopter support, buggies and winch retrieval, or combinations of the above techniques.

Smaller equipment capable of being winched down the slope, or which can traverse steep slopes is most appropriate. The Spyder excavator used for the test pit excavations and piezometer installations was able to move in all directions on the slopes under its own power. It was also able to relocate from BBDA-1 to -2 via a beach route. Depth of excavation with the Spyder was only limited by the lack of shoring.

In certain areas, removal of bedrock may be required to improve site access or equipment anchoring. In general, it appears that if any of the bedrock requires removal, excavation of bedrock will be relatively difficult and expensive and will expose more ground to erosion by removal of vegetation. Consequently, bedrock removal should be limited wherever possible. In general, it appears that if any of the bedrock requires excavation it can likely be removed by large bulldozers such as a D9 with single-tooth ripper, or an excavator. Localized harder zones, such as those encountered along the bluffs at BBDA-1, could be encountered at shallow depths and may require the use of special equipment such as jackhammers, rock splitters or hoe rams.

Waste fill and associated native soils can be removed along the bluff top using conventional earthmoving equipment. This equipment may include rubber-tire or track mounted backhoes and excavators. Most debris can be loaded directly into trucks entering directly from Merchant Road.

At BBDA-1A, there is limited access along trails so that waste material cannot be removed using conventional earthmoving equipment. Instead, equipment may include light-duty rubber-tire or track mounted backhoes, buggies, and bobcat excavators that move waste across the roof of Battery Marcus Miller, down a chute to be loaded into trucks.

8.2.4.6 Temporary Slopes

Because of the sloping bedrock surface and variations in soil depths across the site, excavation of waste fill will expose variable thicknesses of soil and rock. In addition, the thickness of the waste fill and deep excavations (>10 feet) on existing slopes are moderately to very steep (>1:1) are anticipated in the Phase I work areas. It is not practical to begin excavations at the lower portions of the excavation due to the risk of slope movement from above into the lower excavations.

A significant stability concern is potentially adverse bedding (or other planes of weakness) and of the existing landslide and mélange bedrock present in Franciscan bedrock. Adverse bedding can cause rock wedges to fall into the excavation. This can be mitigated by careful observations of a CEG during construction to check exposed conditions and identify potentially adverse bedding, if present. In addition, the CEG would check for other features of concern, such as adversely dipping shear zones. Any safety concerns identified would be relayed to the project team and mitigation such as removal, or rock scaling would be implemented.

It is recommended that temporary cut slopes be limited to a 1:1 (horizontal:vertical) inclination or flatter in native, cohesive soils exhibiting no seepage. In situations with seepage or non-cohesive soils, slopes

should generally be no steeper than 2:1. Slopes greater than 10 feet in height could require intermediate benches of 6 feet in width.

For personnel entry into excavations, excavations should be shored or sloped per Occupational Safety Health Administration (OSHA) and other Health and Safety requirements.

8.2.4.7 Permanent Slopes

Permanent slopes inclinations should be no steeper than 2:1 (horizontal:vertical) for properly compacted fills. Permanent cut slopes in fills, native soils and weathered rock should also be no steeper than 2:1, if practical. Where steeper slopes are required to reduce excavation of materials other than waste fills, slope erosion and or instability over time will probably occur. Permanent cut slopes in sound rock, such as unweathered serpentinite, can be a steep as 1:1 with a lesser potential of instability.

8.2.4.8 Earthwork

Earthwork could include temporary fills for staging of equipment and stockpiles at the tops of the bluffs. This will include special grading (i.e., soil caps) required for protection of historical fill or batteries. Berms for sediment retention basins and permanent fills could also be needed to accomplish remediation objectives.

Temporary Fills

Compacted temporary fills could be used to achieve firm unyielding haul roads, sediment retention berms, crane pads, and protective caps over historical fills and existing roadways. Temporary fills should be constructed as follows:

- Efforts should be made to reduce the disturbance of native soil during construction because this soil is an important resource for restoration plans that include planting native plants in the area. However, it will be necessary to excavate and remove some native soil to complete the removal of waste fills. Native soil that has been removed should be used as much as possible where temporary fills are needed to reduce the use of import fills from offsite. This is especially relevant near the base of the bluffs, where it will be difficult to bring import fill materials to the work areas, such as retention basin berms created at the toe of BBDA-1 and BBDA-2.

- In areas of the site that are soft or that require protection during the remedial actions, appropriate geotextile, filter fabrics should be placed, and covered with compacted fill (an alternative would be to use rubber protection devices). This could include historic fill that is to be protected in the bluff top areas near Battery Marcus Miller and Magazine 21, Battery Boutelle, and Battery Godfrey.

- If imported fill is used for temporary fills, it should meet the requirements for permanent fill materials (non-expansive, preferably granular material) so that it can be reused for permanent fill if necessary.

- Temporary fill soils should be compacted to at least 85 percent relative compaction (based on a maximum dry density determined by the ASTM D 1557 test method). Moisture content should be adjusted to near optimum moisture content as required to achieve compaction.

Permanent Fills including Roads, Pathways, and Parking Areas

It is not anticipated that there will be need to import significant amounts of permanent fills in the bluff and slope areas after remediation. However, the quantity of required permanent fill and its placement will not be known until the waste fill has been removed and slope conditions evaluated.

Permanent fill will be required for improvements to Merchant Road. Design requirements for this are included in *Merchant Road Improvements from Lincoln Blvd. to Toll Plaza, Presidio San Francisco, California* (*MACTEC, 2005j).*

8.2.4.9 Surface Drainage and Erosion Control

It is important to avoid excavation and grading activity during wet weather. Loose soil should be stored outside of drainage pathways. Soil disturbance should be limited to work areas. It is important, even if working under dry conditions, that erosion control measures be in place at the beginning of work and should be maintained at all times, regardless of weather conditions.

There are several potential sources of surface water runoff from the remediation areas during and after the work is performed. Recommended mitigation measures include:

- **Exposed cut and fill slopes:** The design should include stabilization practices such as wattles, silt fences, berms, and temporary outlet protection, as appropriate. The method chosen should depend on the planned activities and erosion potential of the area in question.
- **Excavated soil:** Areas where soil has been excavated should be graded such that storm water runoff will be minimized from the area until the exposed soils are removed.
- **Wet season construction:** Downslope work should not be performed during the wet season due to slope instability and erosion.
- **Areas above slopes:** Where possible, the ground above remediated slopes should be graded to drain away from disturbed areas where vegetation is not fully re-established.

Measures to provide erosion control during site remediation should be in accordance with the following:

- Avoid excavation and grading activity during wet weather;
- Loose soil shall be stored outside of drainage pathways; and
- Soil disturbances should be limited to work areas.

Erosion control measures might include wattles and weed-free straw. Erosion control measures should be in place at the beginning of work and should be maintained at all times, regardless of weather conditions. Imminent rainfall could require the deployment of additional erosion control measures.

8.2.4.10 Site Restoration

After removal of waste fill, temporary erosion control structures, and materials, a permanent vegetative cover is planned for the disturbed slopes. The type of cover, density, and application will be performed under the direction of the NPS.

Placement of the vegetative cover should be in areas that have the required minimum amount of soil, but not on existing trails nor in areas of heavy potential runoff where foot traffic and water erosion would prevent vegetation from becoming re-established. In these areas, onsite rocks can be used to reduce

gullying of soil. Natural retention structures (basins) and rock barriers (berms) might be necessary as part of the post-remediation to reduce impacts from surface water runoff or possible rock falls down onto the beach.

8.3 Cultural Resources Mitigation Plan

As discussed in Section 8.1, there are several areas where historic fill, either displaced or in-place, is in contact with contaminated waste materials. As a result, it is likely that this fill will need to be removed and disposed offsite. The following presents excerpts from the CRI that discuss potential impacts to cultural resources during the planned remedial action and the proposed approach to mitigating potential impacts.

BBDA 1A

BBDA 1A – Located on coastal slope west of north end of Battery Marcus Miller.

The material that will be removed consists of a shallow layer of discarded roofing material that was removed from Battery Marcus Miller. The materials are located in the area that was historically the frontal slope of Battery Marcus Miller and the natural slope that extends westward from the battery complex. Following removal of the roofing material and related debris, the surface will be re-configured to conform to the existing gradient of the frontal slope of Battery Marcus Miller, or to the natural landform. The foot trail will be redefined through the areas of remediation. Monitoring by a qualified archaeologist is recommended to ensure preservation of any remnants of the former frontal slope.

BBDA 1

BBDA 1 – This disposal area is located between Batteries Marcus Miller and Boutelle in the area that was the former location of West Battery mortar pits XLV - XLII. The area is bound on the north by Magazine 21 and on the south by Magazine 22, the Covered Way to the east, and the shoreline to the west. The area of historical interest is located between the two magazines and westward from the Covered Way to the edge of the bluff.

Removal of the fill from the west-facing slope, poses no immediate adverse effect to the resources identified on the bluff above the fill area. Concerns regarding slope stability and related potential effects to Battery Boutelle are recognized, and instrumentation will be placed at Battery Boutelle during remediation activities to provide substantial and comprehensive data with respect to any changes in the existing condition.

On the bluff top in the historic location of the mortar platforms, parapet, and frontal slope, fill soils will be removed to a depth consistent with the chert layer that for the most part blankets the entire site. This layer is thought to be sufficiently thick and/or is located high enough above the resource, to act as a protective cap to the original construction and landforms that comprise this section of the fortification.

In the vicinity of the incinerators, on the western margin of the area adjacent the bluff, excavation to remove contaminated soils, where the chert layer was not encountered, may require removal of a portion of the earthworks related to Magazine 21 and the frontal slope. Monitoring will be required during all soil removal to ensure that no undue damage occurs to the earthworks.

The end condition will involve reconfiguring of the ground surface in a manner that conforms to, or reflects, the topography recorded in the 1902 plans of the “Battery Commander Station for Battery Cranston” (Figure 44 of the CRI Report; Appendix B). That plan appears to reflect the post-Endicott

modifications to the surrounding earthworks but retains the bench that was the location of the mortars, the parapet and the frontal slope characteristic of the West Battery period. Elevations provided by the drawing correspond relatively well to the existing condition, in that the upper most surface of Magazine 21 is shown as 222 feet, and the elevation of that feature was recorded during the 2005 field investigation as being 220 feet. Reconfiguration of the existing landform will look to restoring the parapet and frontal slope in the vicinity of the mortar platforms between Magazines 21 and 22.

Some in-field effort also will be required to create conformance of the grades in the vicinity of the granite threshold stone at the entrance of Magazine 21 and the four mortar pit locations to the south of the magazine.

It is recommended that trained archaeologists monitor the remediation and reconfiguration activities to ensure that the expected subsurface condition is consistent with the profiles revealed during the test phase and that no damage accrues to unanticipated resources.

BBDA 2A

BBDA 2A – This remediation area is located on the coastal slope toward the middle of Battery Godfrey. Remediation activities in this area are not anticipated to have any adverse effect on the resources located on the bluff top.

BBDA 2

BBDA 2 – This remediation area is located at the south end of Battery Godfrey, essentially between Magazines 28 and 29 and extends north into the existing parking lot, and west, to and over the bluff. Based on the profiles revealed during the testing conducted in mid-2005, the removal of the waste fill will have no impact to the remaining historic resources in the vicinity.

Evidence of the frontal slope (specific identification as to whether this is associated with the Battery West fortifications or the subsequent Endicott Period fortifications has not been established) has been identified in the parking lot area (see prior discussion and profile drawings). Pending resolution of the disposition of the parking lot and general planning issues, consideration should be given to re-configuring that area to conform to the historic gradient consistent with the frontal slope of the Endicott period fortifications.

(1) = The GPS unit was used to locate soil borings on a surveyed topographic map, this map was used to obtain accurate boring elevations.
(GPS unit has a accuracy of + or - 5ft for vertical distances)
ft = feet
PLLW = Presidio Lower Low Water
bgs = below ground surface
UA = Undesignated Area
GPS = Global Positioning System
CB/FRP = Elevation measured from the closest building or a fixed reference point.

Table 3. Abridged Modified Mercalli Intensity Scale
Field Investigation Report
Baker Beach Disturbed Areas 1, 1A, 2, and 2A
Presidio of San Francisco, California

I.	Detected only by sensitive instruments.
II.	Felt by a few persons at rest, especially on upper floors; delicate suspended objects may swing.
III.	Felt noticeably indoors, but not always recognized as a quake; standing autos rock slightly, vibration like passing truck.
IV.	Felt indoors by many, outdoors by a few; at night some awaken; dishes, windows, doors disturbed; motor cars rock noticeably.
V.	Felt by most people; some breakage of dishes, windows, and plaster; disturbance of tall objects.
VI.	Felt by all; many are frightened and run outdoors; falling plaster and chimneys; damage small.
VII.	Everybody runs outdoors; damage to buildings varies, depending on quality of construction; noticed by drivers of autos.
VIII.	Panel walls thrown out of frames; fall of walls, monuments, chimneys; sand and mud ejected; drivers of autos disturbed.
IX.	Buildings shifted off foundations, cracked, thrown out of plumb; ground cracked, underground pipes broken.
X.	Most masonry and frame structures destroyed; ground cracked; rails bent; landslides.
XI.	New structures remain standing; bridges destroyed; fissures in ground; pipes broken; landslides; rails bent.
XII.	Damage total; waves seen on ground surface; lines sight and level distorted; objects thrown up into air.

Table 4. Piezometer Water Level Measurements
Field Investigation Report
Baker Beach Disturbed Areas 1, 1A, 2, and 2A
Presidio of San Francisco, California

Piezometer No.	Total Depth (ft. TOC)	Depth to Water (ft. TOC)	Depth to Water (ft. bgs)	Date Measured	Comment
BB1PZ100	18.15	NA	NA	4/21/2005	Constructed, Screened in bedrock
		4.05	1.25	5/23/2005	Developed
		4.04	1.24	5/27/2005	
		4.02	1.22	8/1/2005	
		4.18	1.38	10/4/2005	
		3.48	0.68	2/1/2006	Sampled
BB1PZ101	12.5	NA	NA	4/22/2005	Constructed, screened in waste fill
		4.77	2.22	5/23/2005	Developed
		4.5	1.95	5/27/2005	Additional Development
		5.32	2.77	8/1/2005	
		5.03	2.48	10/4/2005	
		4.63	2.08	2/1/2006	Sampled

Key:
ft = feet
TOC = Top of Casing
bgs = below ground surface
NA = Not Applicable

Checked
Approved MJH

Notes:
1. The top of casing elevation for piezometer BB1PZ100 differs 40 ft from that of BB1PZ101.
2. TOC elevations for BB1PZ100 and BB1PZ101 are 104 ft and 64 ft respectively.

(1)Soil Cleanup Levels were determined by comparing COC cleanup levels for protection of human health, ecological receptors, and groundwater resources and using the most stringent of these three; unless the background concentration for the particular COC was higher and in that case we used the background level as the cleanup level. (EKI, 2002)

(2)Seep Water Cleanup Levels were determined by comparing drinking, freshwater, and surface water cleanup levels and choosing the most stringent. (EKI, 2002)(RWQCB Basin Plan, 11-17- 2004)

mg/kg = milligrams per kilogram µg/L = micrograms per liter

Table 6. Definition of Qualifiers
Field Investigation Report
Baker Beach Disturbed Areas 1, 1A, 2, and 2A
Presidio of San Francisco, California

Summary of Analyte Qualifiers Used in this Report

Type	Qualifier	Qualifier Description — Qualifiers are listed as validation qualifier / lab qualifier where applicable (e.g. J/J+)
Inorganic/ Organic	J	Data are qualified as estimated. It is not possible to assess the direction of the potential bias. False positives or false negatives are unlikely to have been reported.
Inorganic/ Organic	J-	Data are qualified as estimated, with a low bias likely to occur. False positives or false negatives are unlikely to have been reported.
Inorganic/ Organic	J+	Data are qualified as estimated, with a high bias likely to occur. False positives or false negatives are unlikely to have been reported.
Inorganic/ Organic	U	Data are qualified as nondetected, because the analyte was observed in an associated laboratory or field blank.
Inorganic/ Organic	A	Data has been validated and no qualifiers were applied.
Inorganic/ Organic	UJ	The analyte was not detected above the reported sample quantization limit. However, the reported quantization limit is approximate and may or may not represent the actual limit of quantization necessary to accurately and precisely measure the analyte in the sample.
Inorganic/ Organic	C	Presence confirmed, but RPD between columns exceeds 40%.
Inorganic/ Organic	b	Analytical problems were encountered. See the associated case narrative in data package from lab.
Inorganic/ Organic	H	Heavier hydrocarbons contributed to the quantification.
Inorganic/ Organic	L	Lighter hydrocarbons contributed to the quantification.
Inorganic/ Organic	Y	Sample exhibits chromatographic pattern that does not resemble standard.
Inorganic/ Organic	YZ	Indicates that quantization is based only on a single peak or peaks and that the chromatogram does not resemble a fuel pattern.
Inorganic/ Organic	Z	Indicates that the chromatogram resembles the requested standard, but includes a single peak that significantly biases the quantization.

Footnotes:

Results exceeding cleanup levels are outlined with a box.

Sample data is provided on a dry weight basis.

ND = Not Detected at the specific reporting level in parentheses.

NT = Not Tested

Analytical tables present results for compounds that were detected in any of the samples collected from the site.

Results for non-detect compounds are listed on tables in Appendix C2.

Checked

Approved MJH

Note: Where validation qualifiers are absent, data was used for screening purposes.

Footnotes: (1) Cleanup level is EPA Region IX PRG, because there is no Presidio cleanup level for this compound.
(2) Results are compared to cleanup level for total chlordane; results are added to evaluate if there is an exceedance.

Indicates analytical result exceeds cleanup level

Sample numbers have date sampled incorporated into the end of the identification number to create a unique sample identification for database management purposes

UF at the end of the sample number means the sample collected for metals analysis is unfiltered

Cleanup levels are the most stringent of drinking water, freshwater seep, and surface water cleanup levels from EKI, 2002 and the RWQCB Basin Plan (RWQCB, 2004)

* exceeds drinking water cleanup level; cleanup level is for dissolved metals and is therefore considered applicable to filtered samples only

**exceeds surface water cleanup level; cleanup level is for dissolved metals and is therefore considered applicable to filtered samples only

(b) from RWQCB Basin Plan dated 11-17-2004

Footnotes:
(1) Cleanup level is for total chlordane.
(2) Gamma-chlordane is the only chlordane coumpound detected;
as a result, the cleanup level for total chlordane may be applied to these samples.

Field Investigation Report
Baker Beach Disturbed Areas 1, 1A, 2, and 2A
Presidio of San Francisco, California

Material Description	Designation for Slope Stability Analyses	Total Unit Weight (pcf)	Short Term Analysis (Total Strength Parameters)		Long Term (Effective Strength Parameters)	
			Cohesion or Undrained Strength (c, psf)	Internal Friction Angle (phi, deg)	Cohesion or Undrained Strength (c', psf)	Internal Friction Angle (phi, deg)
Waste Fill	**afw**	125	700	0	0	30
Waste Fill	**afw**	125	0	36-39[a]	0	36-39[a]
Historical Fill (clayey)	**afh, afh1, afh2**	125	1,000-2,000[b]	0	0	32
Historical Fill (sandy)	**afh, afh1, afh2**	125	200	22	0	35
Colma Fm/Native Soils (Qcol, clayey)	**Qcol1**, 0-10 ft	130	1,200	0	0	30
Landslide Deposits	**Qls**	120	0	39	0	39
Colma Fm/Native Soils (Qcol, clayey)	**Qcol2**, 10-20ft	130	1,200-2,500	0	0	30
Colma Fm/Native Soils (Qcol, clayey)	**Qcol3**, >20ft	130	2,500	0	0	30
Colma Fm/Native Soils (Qcol, sandy)	**Qcol1** to **Qcol3**	130	150	30	0	30-35[b]
Bedrock, Melange units (KJm)	**KJm**	131	3,000	0	3,000	0
Bedrock, including serpentinite	**sp**	120	10,000	0	10,000	0
Bedrock, including serpentinite	**sp1**, 0-5ft	120	500	0	500	0
Bedrock, including serpentinite	**sp2**, 5-12ft	120	500-750	0	500-750	0
Bedrock, including serpentinite	**sp3**, 12-25ft	120	750-2,000	0	750-2,000	0
Bedrock, including serpentinite	**sp4**, >25ft, and in prominent cliff faces	130	2,500	0	2,500	0
Historical Fill (clayey)	**afh, afh1, afh2**	125	800-2,000[b]	0	0	32

a Use higher strengths (friction angle = 36-39 degrees) where determined by slope geometry

[b] Varies by location

Notes:

psf - pounds per square foot

pcf - pounds per cubic foot

[a] Sample ID will be dated that duplicate is collected.
[b] Number in parentheses corresponds to sample depth in feet.
[c] Both filtered (dissolved metals) and unfiltered (total metals) samples were collected and analyzed.
Dissolved metals include: aluminum, antimony, arsenic, barium, beryllium, cadmium, calcium, chromium, cobalt, copper, iron, lead, magnesium, manganese, nickel, potassium, selenium, silver, sodium, thallium, vanadium, zinc, and total dissolved solids.
Total metals (unfiltered) also include the above analytes.

EXPLANATION

Artificially Deposited Fill

afh – Historic fill; human-placed fill associated with the construction of the Earthen Barbette Batteries or Endicott Period Batteries. Generally defined as including the areas of "superior slope" and "traverses" of the earlier Barbettes, as well as beneath the sod placed on the shoreside surface of the Endicott Batteries. For clarity, it also includes the concrete Endicott Period bunkers. May contain cultural artifacts and select earth materials of significance

afh1 – Historic fill; in place.

afh2 – Historic fill; disturbed.

afw – Waste fill; human-placed fill (landfill) associated with dumping of demolition debris and residential waste over the edge of the coastal bluff and limited areas of the Covered Way. Generally defined as including surface observations of concrete, metal, glass, brick, asphalt, roofing slate. May be mixed in a soil matrix of either native (colluvium or beach deposits) or non-native (chert road fill, bedding sand, etc.) May contain Chemicals of Concern (COC) above cleanup levels.

afo – Other fill; human-placed fill of uncertain origin. Generally found outside historic boundaries of the Earthen Barbette Batteries or Endicott Period Batteries boundaries. Also contains engineered fill placed for roads within the Area of Potential Effect (APE).

afo1 – Other fill; human placed fill with construction debris.

Quaternary Deposits

Qls – Landslides deposits; where exposed may contain rafts of afw and/or afo. Characterized as slump or rotational on the lower slopes; as talus or localized rockfall at base of Serpentinite cliffs.

Qcol – Native Soils, includes residual bedrock soils and Colma Formation, consisting of unconsolidated clean sand and clayey sand deposits. Also includes colluvium - native slope-wash materials consisting of clay, sandy clay and gravelly sand with some cobbles or boulders.

Qb – Beach Deposits; found exclusively in tidal zone, contains variable afw, as well as driftwood and trash.

Bedrock

Franciscan Assemblege

KJm – Melange; contains hetereogenous mixture of greenstone, greywacke sandstone and chert in a sheared soil-like matrix.

KJss and KJsh – sandstone and shale respectively; Large, coherent blocks of greywacke sandstone and silaceous, thinly bedded shale

Sp – Serpentinite; massive, with other ultamafic and metamorphic rocks included schist, amphibolite, and meta-greenstone.

EXPLANATION

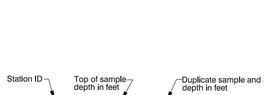
- Geologic Contact, dashed where approximate, queried where uncertain.
- afh — Historic Fill: Endicott period fill that is still in place (afh), disturbed historic fill on bluff top where stippled (afh1), and disturbed historic fill downslope where shaded (ahf2)
- afw — Waste Fill
- afo — Other Fill
- Qls — Landslide Deposits
- Qcol — Colma Fm/Native Soils
- Sp — Serpentinite
- KJm — Melange
- KJss/KJsh — Sandstone Shale
- Qb — Beach Deposit
- Interpreted Extent of refuse - from GPS and EM Survey Data (MACTEC, 2005d)
- E E' — Geologic Cross-Section (see inset map)
- Seep
- BBSB08 — Boring (Pre-2005)
- BB2SB102 — Boring (2005)
- Location Identified to have COCs above Cleanup Levels in Soil
- BB2TP100 — Test Pit



Results for samples collected for this investigation are shown in green typeface. Results shown in **BOLD** type face exceed applicable cleanup levels.

Notes:

1. See Geologic Exploration Map (Plate 2) for location.
2. All previous boring locations are approximate.
3. Basemap was provided by Presidio Trust.
4. "X" = Indicates the chemical exceeds clean-up level at this location.
5. ft bgs = feet below ground surface
6. COC = Chemical of Concern
7. All concentrations in mg/kg.
8. NA = Not Analyzed
9. "J-+" = Estimated High Bias
10. "J-" = Estimated Low Bias
11. "U" = Qualified as No-Detection
12. <0.0078 = not detected at indicated reporting limit.
13. "RES, ECO-SS" = Residential and Ecological - Special Status
14. "*" = Asterisk indicates sample was only analyzed for lead and/or zinc.
15. "**" = Double asterisk indicates sample was only analyzed for lead.
16. Groundwater samples are are not identified on this plate, but are described in the text and analytical results are located on Table 9.
17. There are no Presidio cleanup levels for dioxins and furans; the calculated toxic equivalency value (TEQ) for 2,3,7,8-TCDD exceeds the EPA preliminary remediation goal of 0.0000039 mg/kg and the RWQCB environmental screening level of 0.0000045 mg/kg.
18. Results for alpha- and gamma-chlordane are summed and presented as total chlordane.

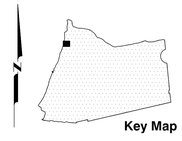


Figure modified from Main Installation Sites Feasibility Study (EKI, 2003). All locations are approximate.

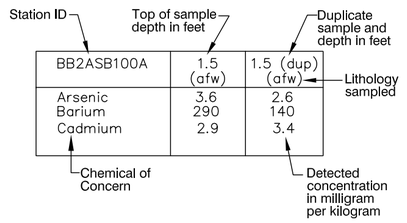
Geologic Cross Section G-G'

EXPLANATION

- Geologic Contact, dashed where approximate, queried where uncertain.
- afh — Historic Fill: Endicott period fill that is still in place (afh), disturbed historic fill on bluff top where stippled (afh1), and disturbed historic fill downslope where shaded (ahf2)
- afw — Waste Fill
- afo — Other Fill
- Qls — Landslide Deposits
- Qcol — Colma Fm/Native Soils
- Sp — Serpentinite
- KJm — Melange
- KJss/KJsh — Sandstone Shale
- Qb — Beach Deposit
- Interpreted Extent of refuse - from GPS and EM Survey Data (MACTEC, 2005d)
- E E' — Geologic Cross-Section (see inset map)
- Seep
- BBSB08 — Boring (Pre-2005)
- BB2SB102 — Boring (2005)
- Location Identified to have COCs above Cleanup Levels in Soil
- BB2TP100 — Test Pit



Results for samples collected for this investigation are shown in green typeface. Results shown in **BOLD** type face exceed applicable cleanup levels.

Notes:

1. See Geologic Exploration Map (Plate 2) for location.
2. All previous boring locations are approximate.
3. Basemap was provided by Presidio Trust.
4. "X" = Indicates the chemical exceeds clean-up level at this location.

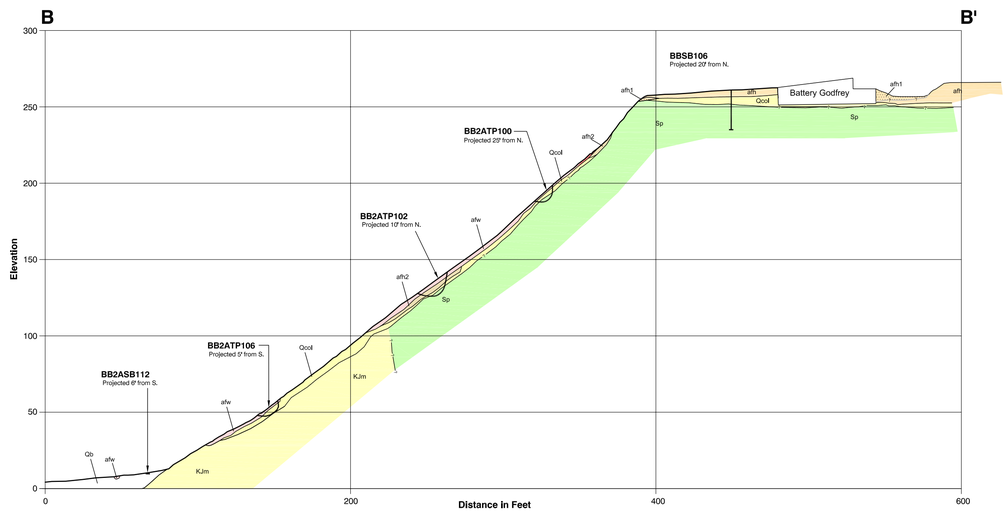
Geologic Cross Section D-D'



Geologic Cross Section B-B'

MACTEC

EXPLANATION

- Geologic Contact, dashed where approximate, queried where uncertain.
- afh — Battery West Historic Fill: most recent construction and still in place (afh), disturbed on bluff top where stippled (afh1), and disturbed downslope where shaded (afh2)
- afw — Waste Fill
- afo — Other Fill
- Qls — Landslide Deposits
- Qcol — Colma Fm/Native Soils
- Sp — Serpentinite
- KJm — Melange
- KJss/KJsh — Sandstone Shale
- Qb — Beach Deposit
- Interpreted Extent of refuse - from GPS and EM Survey Data (MACTEC, 2005d)
- E E' — Geologic Cross-Section (see inset map)
- Seep
- BBSB08 — Boring (Pre-2005)
- BB2SB102 — Boring (2005)
- BB2TP100 — Test Pit
- Location Identified to have COCs above Cleanup Levels in Soil
- Bedding Attitude
- Joint Attitude

Station ID | Top of sample depth in feet | Duplicate sample and depth in feet | Lithology sampled

BB2ASB100A	1.5 (afw)	1.5 (dup) (afw)
Arsenic	3.6	2.6
Barium	290	140
Cadmium	2.9	3.4

Chemical of Concern | Detected concentration in milligram per kilogram

Results for samples collected for this investigation are shown in green typeface. Results shown in **BOLD** type face exceed applicable cleanup levels.

Notes:

1. See Geologic Exploration Map (Plate 2) for location.
2. All previous boring locations are approximate.
3. Basemap was provided by Presidio Trust.
4. "X" = Indicates the chemical exceeds clean-up level at this location.
5. ft bgs = feet below ground surface
6. COC = Chemical of Concern
7. All concentrations in mg/kg.
8. NA = Not Analyzed
9. "J+" = Estimated High Bias
10. "J-" = Estimated Low Bias
11. "U" = Qualified as No-Detection
12. <0.0078 = not detected at indicated reporting limit.
13. "RES, ECO-SS" = Residential and Ecological - Special Status
14. Seepwater samples are are not identified on this plate, but are described in the text, and analytical results are located on Table 9.

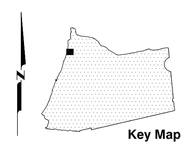


Figure modified from Main Installation Sites Feasibility Study (EKI, 2003). All locations are approximate.

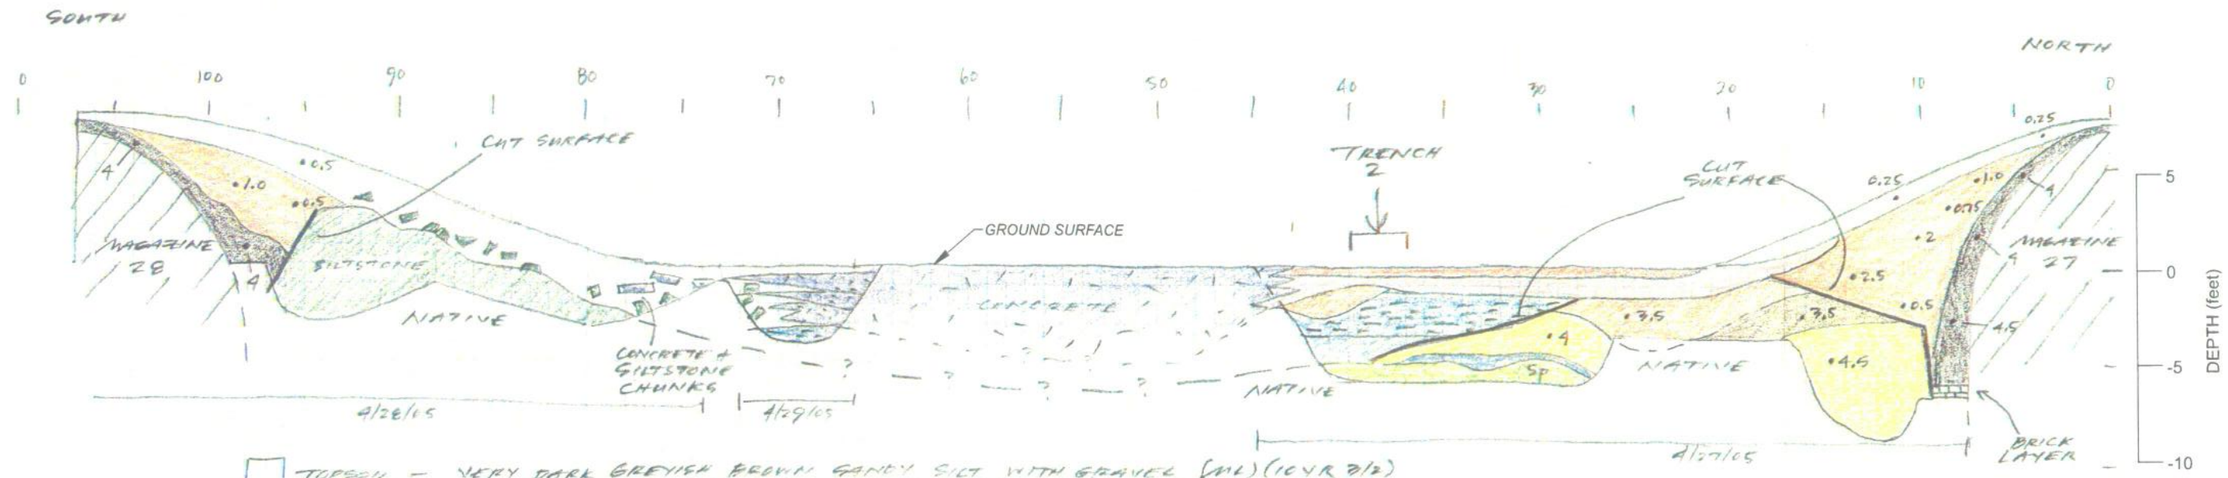
APPENDIX A

EXPLORATORY LOGS

APPENDIX A1

EXPLORATORY TRENCH LOGS

Trench 1



TOPSOIL – VERY DARK GREYISH BROWN SANDY SILT WITH GRAVEL (ML)(10YR 3/2) SOFT, DRY TO MOIST, GENERALLY 60% SILT 20% SAND 20% GRAVEL

MIXED CLAY FILL – MIXTURE OF YELLOWISH BROWN (10YR 5/6) AND VERY DARK BROWN (10YR 2/2) LEAN CLAY (CL) SOFT, MOIST., 80% CLAY 20% SILT, OCCASIONALLY SANDY.

CONSTRUCTION CLAY – BLACK LEAN CLAY (CL) (10YR 2/1) HARD TO VERY HARD, MOIST. 100% CLAY. COMPACTED ON SIDES OF STRUCTURES.

CONCRETE – MULTIPLE LAYERS OF CONCRETE AND CEMENT GROUT (SOME WITH COLOURING AGENTS ADDED) PRESUMED TO BE AN OLD WASH OUT AREA.

CHERT FILL (1) – DARK REDDISH BROWN WELL-GRADED GRAVEL WITH SAND (GW)(5Y 3/2) DENSE, DRY. 70% GRAVEL (ANGULAR CHERT TO 1.5" Ø) 20% SAND <10% FINES

CHERT FILL (2) – AS ABOVE, BUT LIGHTER COLOUR - REDDISH GREY (5Y 5/2)

FILL SAND (1) – VERY DARK GREY POORLY GRADED SAND WITH CLAY INCLUSIONS (SP)(5Y 3/1) LOOSE TO MEDIUM DENSE, DRY TO MOIST. 70% SAND. 30% YELLOWISH BROWN CLAY.

FILL SAND (2) – VERY DARK GREY POORLY GRADED SAND (SP)(5Y 3/1) LOOSE TO MEDIUM DENSE. MOIST. 100% SAND.

NATIVE MATERIALS

SILTSTONE – OLIVE GREY SILTSTONE (5Y 5/2)( ) MODERATELY CONSOLIDATED. CLOSELY FRACTURED LOW HARDNESS. WEAK, DEEPLY WEATHERED

CLAY (1) – VERY DARK GREYISH BROWN LEAN CLAY (CL) (10YR 3/2) HARD, MOIST. 80% CLAY 15% SILT 5% VERY FINE CHERT SAND.

CLAY (2) – YELLOWISH BROWN LEAN CLAY (CL) (10YR 5/6) HARD, MOIST., 100% CLAY. WITH FeO_2 MOTTLE, AND BLACK OXIDATION ALONG FRACTURES. IN PLACES RESEMBLES WEATHERED ROCK.

SAND – DARK GREYISH BROWN SILTY SAND (SM) (2.5Y 4/2) DENSE, WET. 60% VERY FINE SAND 40% SILT/FINES. HAS BEDDING PLANES. THIN LAMINATIONS.

SERPENTINITE – LIGHT OLIVE BROWN (2.5Y 5/3) TO GREENISH GREY (5GY 5/1). MODERATELY CONSOLIDATED. INTENSELY FRACTURED. LOW TO MODERATE HARDNESS. FRIABLE TO WEAK. DEEPLY WEATHERED.

• 4.5 – POCKET PENETROMETER

APPENDIX A2

TEST PIT LOGS

(1) Dark brown clayey sand (SC) (10YR 3/3) Soft, wet. 60. Clay/fines, 20% Gravel, 20% Sand. Little refuse, fill soil.

(2) Dark yellowish brown clayey sand (SC)(10YR 4/4) Loose, wet. 70% Fine sand, 30% Silt/Fines.

(3) Very dark greyish brown sandy fat clay (CH) (10YR 3/2) soft wet. 50% Clay, 30% Sand, 20% Silt. With debris in layers, metal, glass, asphalt, tar, wood, sweater/cloth fragments, spark plug.

FIGURE **A3-1**

DRAWN	JOB NUMBER	CHECKED	CHECKED DATE	APPROVED	APPROVED DATE
CN	57255 004122		12/05	may	6-8-06

RELATIVE DENSITY OF COARSE-GRAINED SOILS

Relative Density	Standard Penetration Test Blow Count (blows per foot)
very loose	<4
loose	4-10
medium dense	10-30
dense	30-50
very dense	>50

CONSISTENCY OF FINE-GRAINED SOILS

Consistency	Approximate Blows/Foot (SPT)	Undrained Shear Strength (psf)
very soft	<2	0 - 250
soft	2-4	250 - 500
medium stiff	4-8	500 - 1,000
stiff	8-15	1,000 - 2,000
very stiff	15-30	2,000 - 4,000
hard	>30	>4,000

NATURAL MOISTURE CONTENT

Dry - Requires considerable moisture to obtain optimum moisture content for compaction

Moist - Near the optimum moisture content for compaction

Wet - Requires drying to obtain optimum moisture content for compaction

Note: Where laboratory data are not available, the field classifications given above provide a general indication of material properties; the classifications may require modification based on judgment or laboratory testing.

Re: Draft Final Report for Baker Beach Cultural Resource Evaluation

Dear Mr. Ford:

Enclosed are three copies of the report titled "Cultural Resources Baseline and Impact Assessment for the Baker Beach Disturbed Area (BBDA's) 1, 1A, 2 and 2A Remedial Actions". An electronic copy of this report is available on the URS FTP site, per our prior communications.

Thank you for the opportunity to work on this interesting and challenging project.

Sincerely,

URS CORPORATION

Vance G. Bente

Figures

1	Landfill Location Map: Project Area
2	Area of Potential effects
3	The visibility and vulnerability of masonry works is illustrated by this view of the fort at Fort Point in the Presidio, c1900
4	Prototypical plan of an earthwork drawing: "Plans Sections and Elevations of a Barbette Battery as Proposed by the Board of Engineers for Fortifications," 1868 (NARA RG 77, Drawer 155, Sheet 14)
5	Parts of a Rodman Gun & Carriage
6	Section Through an Emplacement Showing Names of Architectural Features
7	A "Plan of 1870" two gun emplacement at East Battery, Fort Scott, c1910. Note the entrance to the service magazine at right. (GOGA, PARC, FOPO Collection.)
8	A Union 13-inch mortar Model 1861 installed during the siege of Petersburg, VA, in 1864. (NARA)
9	Platform for a 13-inch seacoast mortar, 1870. This is the type of platform installed at West Battery. (NARA, RG 77)
10	Detail from drawing titled "Cross-section of Parapets Shewing [sic]. Their Construction in Sand," 1871. Note the layers of sods, mould, and clayey soil on superior slope. (NARA, RG 77, Drawer 155, Sheet 17)
11	Two views of Endicott batteries at Fort Scott along the former location of West Battery.
12	From left to right are Batteries Boutelle, Marcus Miller, Cranston, and Lancaster. A portion of a trapezoidal 1870s traverse #21 is visible between Batteries Boutelle and Marcus Miller. A WWI cantonment area is visible beyond Battery Boutelle. (GOGA, PARC, Interp Coll)
13	Extent of completed earthwork batteries above Fort Point in 1890. Current Remedial Action project areas are circled.

14 Cross-section of a West Battery emplacement for Rodman guns. The traverse and its service magazine are also shown. (From the engineers' 1870 proposal for barbette batteries above Fort Point.)

15 Aerial view of East Battery before construction of the Golden Gate Bridge toll plaza, showing the covered way and parados behind the emplacements. Battery Lancaster is at lower right. (Courtesy GG Bridge, Hwy & Trans. Dist.)

16 A pair of 15-inch Rodmans in West Battery as portrayed in an 1877 issue of "The Wasp," a satirical San Francisco publication. The accompanying article berated the U.S. Government for wasting money on constructing obsolete fortifications. The artist took several liberties with perspective and location, since Fort Point is not visible at this angle from West Battery. Also, the fort is drawn backwards. (California Historical Society)

17 West Battery in 1880 (GOGA, PARC)

18 A 12-inch rifle in Battery Godfrey at the moment of firing, c1915. The brick entrance to Traverse #27, integrated into Godfrey's earthworks, is visible at lower left. (GOGA, PARC)

19 A pair of 8-inch rifled Rodmans and the covered way behind East Battery, 1915. The buildings of the Panama Pacific International Exposition can be seen in the distance. (GOGA, FOPO Coll)

20 Fort Point and a portion of West Battery as viewed from the bay, c1890. Note the 15-inch Rodmans mounted between the traverses. (California Historical Society)

21 The traverses of West Battery appeared like a serrated edge in this view from Broadway and Lyon Streets in Pacific Heights. A portion of the Presidio's main post is in the foreground. (California Historical Society)

22 Section of original 1870 engineer plan showing Traverses 21 (top) and 22 (bottom) and positions for 13-inch mortars. Remedial Site BBDA 1. (NARA RG 77, Drawer 94, Sheet 102)

23 Three views of Traverse 21, view north. Note also the change in road width and the 3-foot height increase of the open area behind the battery

24 Section "f, 1" through mortar positions, showing original height of road cut behind emplacement. (NARA RG 77, Drawer 94, Sheet 102)

25 The outlines of Traverse 21, its magazine, and the former mortar battery location are visible as dotted lines in this 1902 proposal for an extension of Boutelle. Remedial Site BBDA 1. (PARC, GOGA)

26 1922 incinerator on dumpsite. View looking south. Remedial site BBDA 1. (GOGA, PARC)

27 1934 incinerator. View north. Note excavation into earthworks at right. Remedial site BBDA 1. (GOGA, PARC)

28 Approximate locations of two incinerators: 1922 (lower) and 1934 (upper)

29 The "new" incinerator at the dumpsite, lower right. February 1935. (Courtesy GG Bridge, Hwy & Trans. Dist.)

30 An aerial photo taken in May 1967 documents extensive fill on the former site of both the dump and across the road behind the batteries. A pond of water has apparently formed directly over the dumpsite. The curved outlines of the traverses flanking the former battery are still visible. Remedial Site BBDA 1. (Courtesy GG Bridge, Hwy & Trans. Dist.)

31 Section of original 1870 engineer plan showing Traverses 27 (top) and 28 (bottom), and Rodman positions #58 and #59. Section a – 1 is the site of the present overlook access road. Remedial Site BBDA 2A. (NARA RG 77, Drawer 94, Sheet 102)

32 Section "a, 1" through Rodman positions #58 and #59, showing deep road cut (now filled) behind emplacement. (NARA RG 77, Drawer 94, Sheet 102)

33 The three 1870s traverses on the left flank of Battery Godfrey are visible in this February 1942 view. The curved landform between #27 and #28 is a parados constructed to protect the left flank of Godfrey. Tire tracks probably indicate dump activities on the forward slope. Remedial site BBDA 2A. (PARC, GOGA, Cooper Collection)

34 Sections through two portions of Battery Marcus Miller. Note the impressive thickness of the concrete in front of the magazines (upper). (Report of Completed Works, Form 7, Marcus Miller)

35 The terraced superior slopes of Endicott era batteries are visible above Fort Point in this view taken c1900. A 12-inch disappearing rifle at Battery Lancaster appears at left. (California Historical Society)

36 East Battery partly filled in October 1937. Compare to 1984 conditions in Figure 15. (Courtesy GG Bridge, Hwy & Trans. Dist.)

37 Dumping activities occurring near Golden Gate Bridge toll plaza in May 1967. Battery Marcus Miller area at left, East Battery area at right. (Courtesy GG Bridge, Hwy & Trans. Dist.)

The Presidio Trust and the NPS (NPS) are working jointly to plan the removal of landfills known as Baker Beach Disturbed Areas (BBDAs) 1, 1A, 2, and 2A, shown on the illustration of the Historic Battery Survey (Figure 1). The disturbed areas are comprised of soil and debris deposits (landfills) created by 20th century disposal activity along the bluffs. The natural bluffs and cliffs along this portion of the coastline are composed largely of serpentinite bedrock outcrops. Project goals include removal of all contaminated soil and fill material, exposure of serpentinite soils and bedrock, and restoration of native vegetation and habitat. This document provides data pertinent to the cultural resources located on those bluffs and the potential for the undertaking to have an effect on those resources. The Presidio of San Francisco was designated a National Historic Landmark in 1963. The bluffs along this portion of the coastline are the location of 19th century fortifications that contribute to the Presidio's National Historic Landmark status.

Following this introduction, Section 2 presents a brief statement on the general environmental setting of the project area and a description of the Area of Potential Effects (APE). This description is followed by a description and discussion of the resources located along the bluff, both within and adjacent to the disturbed areas. Section 2 also provides a list of properties that are contributing elements to the National Historic Landmark status of the Presidio of San Francisco within the project area.

In Section 3, significant cultural resources are addressed relative to the undertaking, and measures/actions required to complete the characterization/description of those resources are recommended. Additional data are required to sufficiently inform the design documents so as to avoid effect to the resources. Section 4 provides brief comment on the potential for impacts. Section 5 provides a list of the references consulted and cited. Appendices to the document include a report of the intensive archaeological survey of the project APE, an annotated CAD depicting the disturbed areas as currently mapped and the structures and landforms that historically comprised the resources, and a compilation of the data used in the formulation of this report.

1.1 REGULATORY BACKGROUND

Fort Point and the Presidio are both parts of the Golden Gate National Recreation Area (GGNRA), and the BBDA is within the NPS legislated jurisdiction. Both the NPS and the Presidio Trust, the agency conducting the BBDA remediation project, have Programmatic Agreements for their cultural resource management processes, which were mutually developed between these two agencies, the California Office of Historic Preservation, and the Advisory Council on Historic Preservation. Cultural resource assessments for the BBDA have been conducted in a manner that meets the processes established within these Programmatic Agreements and parallels federal agency responsibilities under the National Historic Preservation Act (as amended 1992) as promulgated at 36CFR800 (Protection of Historic Properties). The data provided here will be used in the compilation of relevant sections of a California Environmental Quality Act Initial Study, required by the Department of Toxic Substances Control, and a Presidio Trust Project Screening.

2.1 THE PROJECT AREA

The project area is located within the Coastal Bluffs Planning Area of the Presidio of San Francisco. The Golden Gate Bridge Highway and Transportation District (GGBHTD) use area forms the project boundary to the north, and Lincoln Boulevard and the Pacific Ocean constitute the project boundaries to the east and west, respectively. The southern boundary is approximately 250 feet southern of the south end of the parking area at Battery Godfrey. BBDAs 1, 1A, 2, and 2A are situated immediately west of Endicott Era Batteries Marcus Miller, Boutelle, and Godfrey, and overly portions of the 19th century West Battery.

The BBDA 1, 1A, 2, and 2A project falls within the boundaries of the Presidio of San Francisco National Historic Landmark District (designated in 1963), managed by both the NPS and the Presidio Trust. It is also immediately adjacent to, and historically associated with, the Fort Point National Historic Monument (designated in 1970) and the Golden Gate Bridge National Historic Landmark (determined eligible for listing on the National Register of Historic Places in 1998). As such, many of the significant historic properties within the project area were originally identified and documented by previous surveys, which extend back to the 1960s. Additional research was conducted through the Presidio Trust, URS, and the NPS to acquire greater detail on these historic properties to inform the design of the Remedial Action Plan for the BBDA. The findings of this work are summarized here and recommendations for the completion of treatment of significant historic properties are designed to ensure that no adverse effect would result from project actions to properties contributing to either the Presidio or that might be individually eligible for listing on the National Register of Historic Places.

Other than the cultural landscape comprising the 1870s and 1890s coastal artillery fortifications, the project area consists of open space natural areas overlooking the Pacific Ocean. The area is covered by dense vegetation consisting primarily of introduced species that mask the natural as well as much of the man-made landforms along the bluffs. The majority of the natural growth directly around the batteries emerged in the latter half of the 20th century, outside of the period of significance of the batteries or the Presidio National Historic Landmark (1776-1945). The Coastal Trail runs along the top of the bluff and passes through portions of BBDAs 1, 1A, 2, and 2A. A number of smaller nonmaintained trails are also found in the project area.

2.1.1 The Area of Potential Effects

The APE (Figure 2), for purposes of the cultural resources investigation, was initially established at a preliminary planning meeting on March 5, 2004. The subsequent APE was confirmed at a meeting conducted on April 7, 2004. Participants at the meeting included Ms. Sannie Osborn (Trust), Mr. Leo Barker (NPS), and Mr. Vance Benté (URS). In July 28, 2004, the APE was revised to encompass the area identified to accommodate the relocation of Merchant Road.

The area as depicted on Figure 2 can be described as follows:

> From a point along the high tide line the boundary of the area of potential effects runs north, and then turns northeast, for 500 feet, and east, for about 150 feet, to intersect with the southwest side of the Golden Gate Bridge, following along the

Bridge's southeast side for approximately 300 feet; then turning southwest for 80 feet along the edge of the Golden Gate Bridge District property, and then turning south for 240 feet along the western edge of the district's property, then turning southeast through the district's parking lot to the opposite end, some 320 feet, to a point on Merchant Road.

Following Merchant Road northeast 160 feet, and then following the edge of the undeveloped land to a point on the left side of Highway 101 and the overpass over Lincoln Boulevard; there it turns south-southwest and follows Lincoln Boulevard to Storey Road, turning south for 70 feet, and southwest for approximately 120 feet, then southwest for 200 feet, and then west approximately 130 feet crossing Lincoln Boulevard and following along the left side of Lincoln Boulevard to a point approximately 120 feet south of Langdon Court and there turning west for 200 feet, and then turning south, then southwest, and then south for some 500 feet to a point on the west side of Lincoln Boulevard.

And then turning west, then northwest for 450 feet, and then north-northwest for 490 feet to the coastline. The APE fronts on the coastline for some 1,400 feet.

2.2 PREHISTORIC SETTING

Human occupation in the San Francisco Bay Area may extend back as far as 8,000 years. Archaeological remains in the city of San Francisco date to about 5,000 before present. Carbon dates from sites in the Crissy Field area of the Presidio of San Francisco, approximately ¼ mile east of the project area, demonstrate that native people lived in this locale at least 1,300 years ago (Alley et al. 1993; Clark 2001; Giambastiani and Fitzgerald 2001). Historically, the indigenous culture living in this area of Central California is known as the Costanos, Costanoans, and/or more recently Ohlone (Levy 1978). The specific subgroup living in the San Francisco vicinity were known ethnohistorically as the Yelamu, a semisedentary foraging people living in three village clusters around Mission Creek, Visitacion Valley, and the northwestern tip of the peninsula. This last cluster is associated with one specific village area called Peltlenuc, which existed somewhere along the northern tip of the San Francisco peninsula, perhaps in the Presidio of San Francisco (Milliken 1995:61-63).

In 1993, the NPS established management zones within the Presidio of San Francisco to facilitate its approach to the identification and preservation of both historic and prehistoric archaeological resources (Alley et al. 1993). Zones identified as potentially containing prehistoric sites included the Lobos Creek drainage, the low bluffs and marshlands along Crissy Field, the watershed of Tennessee Hollow, and the spring drainage running from the area of Infantry Terrace to Crissy Field – currently buried beneath the western Parade Ground of the Presidio's Main Post. In about 1998 the high bluffs above Baker Beach, Fort Point, and the west end of Crissy Field were added as possible zones of prehistoric occupation, as well as a major spring drainage on the northeastern side of Fort Winfield Scott.

All of the above areas of prehistoric sensitivity are included in the cultural resources inventory of the Presidio National Historic Landmark District, and both the Presidio Trust and the NPS have used these expected resource areas and contributing historic property inventories in Programmatic Agreements with both the California Office of Historic Preservation and the

Advisory Council on Historic Preservation for the management of cultural resources within the Presidio under the National Historic Preservation Act.

Given the great landform modifications required by the construction of Batteries West, Godfrey, Boutelle and Marcus Miller, it is unlikely, had there been occupation sites or activity areas attributable to Native Americans in the project area, that evidence of that activity would have survived to present day. Possible evidence of prehistoric use of the area is limited to observations of isolated shell fragments in the southern APE between two 1870s powder magazines. That this shell represents prehistoric activity has not been confirmed. During a two-day reconnaissance of the area, the intent of which was primarily to gather information pertinent to the historic period built environment, no evidence of prehistoric use of the area was observed. However, it should be noted that observation was limited to areas of low grass immediately adjacent to the bluffs, and the numerous trails that crisscross the project area. By far, the majority of the available ground surface not occupied by a structure is covered in dense, often impenetrable vegetation that prohibits visual inspection.

2.3 HISTORIC SETTING

2.3.1 Research Goals and Sources

Numerous sources detail the coastal fortifications within in the APE. Primary among these are a series of Historic Resource Studies, a standard work used by the NPS to provide historic context and to frame the management of historic properties in national parks. At GGNRA, these studies focused on the great array of historic military reservations and fortifications developed to defend the harbor of San Francisco Bay (Lewis 1965; Bearss 1973; Thompson 1979; Thompson 1997; Freeman et al. 1999). Historic maps and photographs available through the GGNRA Park Archives and Records Center (PARC) were also used in this study.

Based on discussions conducted during pre-award meetings, and a subsequent meeting convened to finalize the research design, the PARC and the National Archives at San Bruno were identified as the primary sources of data relevant to the research goals of the project. Seeking additional information from the central National Archives at College Park, MD, was carried out on a limited basis. These efforts were restricted to searches through specific record groups (RGs) where illustrations of San Francisco fortifications were previously known to exist.

2.3.1.1 Research Conducted at the Presidio Archives (PARC)

The focus of the research to be conducted at Presidio Archives included the notes written and compiled by Erwin Thompson for his publication *Historic Resource Study, Seacoast Fortifications,* the research notes used to compile the NPS' *Seacoast Fortifications Preservation Manual*, and the U.S. Army Corps of Engineers records including "completion reports" and armament reports with "as-builts" for West Battery and the Endicott Era batteries.

A general review of the holdings was undertaken to identify a set of high-resolution, historic (1942) aerial photos known as the "Cooper Collection," and any data pertaining to the design, construction, or maintenance of West Battery. The photo collection was not located during the research undertaken for this report, but was subsequently located at the San Francisco Maritime National Historic Park Archive and is addressed in Section 3.

Additional collections reviewed at the Park Archives included the Fort Point Drawing Collection, the historic photograph reference binders, the Harbor Defenses of San Francisco fortification drawing collections, and the "Historical Record Buildings, Fort Winfield Scott."

2.3.1.2 Research Conducted at the National Archives, San Bruno

The National Archives at San Bruno were accessed to recover any data that were additive to the materials recovered from the PARC. Review of the facility's holdings indicated little material pertinent to West Battery, or any other pre-1890 West Coast military installation/fortification among its holdings. Discussion with archivists Robert Glass and John Hedger revealed that nearly all pre-1890 historic military records from the West Coast had been relocated to the National Archives' primary facility in College Park, Maryland. Mr. Glass, National Archives local specialist on seacoast fortifications, confirmed that the facility at San Bruno did not include among its collection "as-builts," photos, or maps of West Battery.

Additional materials, listed under Research Conducted in Section 5 were reviewed to recover any secondary or ancillary information contained there.

2.3.1.3 Research Conducted at the National Archives II, College Park, MD

A contract researcher was enlisted to review specific collections in the cartographic branch of the National Archives II where drawings of generic earthwork batteries and the "Plan of 1870" fortifications constructed above Fort Point were known to exist. These collections were consulted in the hope that additional information would be identified that had been overlooked by previous researchers. These collections were all within Record Group 77, Corps of Engineers, specifically drawer numbers W-9, 93, 94, 97, 155, and 256. Text research was not conducted at the National Archives II due to the fact that historians Bearss and Thompson had already examined these records extensively for earlier Historic Resources Studies.

2.3.1.4 Research Conducted at the Golden Gate Bridge, Highway, and Transportation District Archive

GGBHTD maintains an archive of historic photographs documenting the construction of the bridge beginning in 1933, many of which include views of the adjacent fortifications in Fort Point. These photographs are useful for documenting conditions prior to construction of the toll plaza as well as subsequent building and filling operations behind the batteries. These collections are arranged in chronological order in a series of photo albums, which are maintained by the Director of Public Relations.

2.3.1.5 Research Conducted at the California Historical Society

Numerous photographs of the Fort Scott batteries were located in the collections of the California Historical Society in San Francisco, especially distance views of the earthworks at West and East Batteries. Photo collections consulted were "San Francisco – Presidio," "San Francisco – Fort Point," and "San Francisco – Fort Winfield Scott."

2.3.2 Introduction

The Presidio Trust has commissioned this investigation into the background, context, construction, alteration, and post-military uses of these batteries. The goal is to develop information that will support URS' historic resource studies on this area of the Presidio, which are being prepared to provide documentation on historic resources that may be encountered during remedial actions at the BBDAs in the Presidio of San Francisco. This report on the Presidio batteries will build and expand upon the excellent historic narrative portion of the report *Cultural Resource Baseline and Impact Assessment for the Baker Beach Disturbed Areas* prepared for the Presidio Trust by URS in August 2004.

Major emphasis in the report is given to the history of the 1870s earthworks in the areas designated BBDA 1 (between Batteries Marcus Miller and Boutelle) and BBDA 2A (adjacent to the left flank of Battery Godfrey) because of the documented existence of "Plan of 1870" remnant earthworks and magazines in these areas and the high likelihood of encountering additional resources.

2.3.2.1 Background and Context

The line of gun batteries stretching along the Presidio bluffs south and west from the Golden Gate Bridge toll plaza form an "outdoor museum" of late 19th century fortifications that are rivaled few places elsewhere in the United States. These gun batteries, constructed between 1870 and 1900, show the transitional nature of United States defenses at the time when its harbor fortification system was undergoing the change from "storybook castle forts" filled with muzzle loading cannon to modern low-profile earth and concrete fortifications mounting long-range, rifled steel guns.

These batteries, referred to as "works" by the U.S. Army Engineers who constructed them, represent not only a time capsule of evolutionary military design, but also include some of the earliest of the modernized American fortifications constructed anywhere in this country.

Beginning in 1865, the American military began to reassess its system of harbor defenses. Battlefield lessons learned during the Civil War showed that multitiered masonry forts of the style typified by Fort Sumter in Charleston, South Carolina, and Pulaski at Savannah, Georgia had proven to be highly vulnerable to attack. Built to design standards that went back to the 1820s, these forts – and about 40 other similar works around the United States – were referred to as "Third System forts" because they represented the third generation of American fortification designs. However, during the just-finished war their towering masonry walls had proven to be inviting targets for long-range, rifled artillery fire (Figure 3). Instead of withstanding months of siege, some masonry forts had surrendered after only a few days of bombardment. (Fort Pulaski's Confederate defenders held out for only 30 hours before its 7½-foot thick-walls were penetrated by Union artillery fire.)

In addition, steam-powered warships could race past these masonry fortifications, suffering relatively minor damage to their ironclad hulls, especially when compared to the wind-propelled wooden warships that had been state-of-the-art when the Third System was begun.

The lesson was clear: all these multistoried forts had become obsolete due to advances in military technologies, including the three-story fort at Fort Point in the Presidio of San Francisco,

a work that had only been completed in 1861. These sobering revelations would have impacts both abroad as well as in the United States.

FIGURE 3 The visibility and vulnerability of masonry works is illustrated by this view of the fort at Fort Point in the Presidio, c1900

Historian E.R. Lewis, the preeminent expert in the evolution of America's coastal defenses, summarized the situation in the late 1860s:

> By 1865 several European nations were already starting to respond to the technical lessons of the Civil War by drafting plans for the construction of entirely new, and extremely expensive, types of permanent harbor defenses armored with great masses of iron, thus beginning a trend in military architecture which was to continue well into the 20th century, making use in its extreme instances of shore-mounted battleship turrets.
>
> The United States, however, was in no position to commence an extensive new system of harbor defenses. The planning engineers, mindful of the suddenness with which the existing (i.e., Third System) fortifications had been rendered obsolete, were reluctant for technical reasons to turn to elaborate works that might quickly become outmoded, as there was much to suggest–correctly, as events proved–a coming period of further rapid advances in artillery. Nor would such an undertaking if proposed have stood much chance of realization, for under the extreme postwar stress on reduced military spending, any appropriations large enough to be meaningful would also have been out of the question.

The U.S. Engineers carried out limited testing with armor plates attached to the faces of existing masonry forts, but with disappointing results. Iron plates frequently split or shattered when hit by projectiles, and the sheer weight of the plates presented huge installation problems. Costs were enormous, and one glaring defect in the plan could not be overlooked; as one historian wrote, "The fort was still a large, obvious target, easy to hit." (Williford 2005, pg.3).

Even during these tests, the engineers' thinking was leaning towards a radically new design based upon the simple earthen batteries erected during the Civil War. These emergency works had been constructed of copious amounts of earth and sand cover, and had very low profiles when viewed by an attacking enemy. These improvised fortifications, they noted, had been simple to build, provided excellent protection against enemy fire, and were easy to maintain and repair. Earthworks, they decided, would become be the basis of the next generation of permanent American forts.

In August 1868 the New York Board presented a report concerning the proper profile for postwar barbette batteries. These specifications would be the standards for what came to be called the "Plan of 1870" because of the year of their actual implementation (Figure 4). Historian Erwin Thompson (1979) summarized the 1868 Board's findings:

- As a material for parapets, sand was far superior to clay.
- A parapet of sand, 20 feet between the crests supported by a breast-height wall 4 feet thick, would suffice as a minimum.
- A wall in the body of the parapet was not recommended.
- The introduction of iron plates in parapets was inexpedient except in peculiar cases.
- The minimum distance between 15-inch guns should be 34 feet, and the minimum distance between 10-inch guns should be 22 feet.
- The terreplein should not be less than 30 feet in depth.
- Every two guns exposed to direct or oblique fire and every gun subjected to enfilading fire should have a traverse. When practicable, guns liable to reverse fire should have a parados.
- Minimum dimensions for a traverse should be 14 feet in height, 12 feet in thickness at the top, and 20 feet in thickness at the bottom.
- Service magazines were indispensable. Good well-rammed concrete was the best material, with no lining.

The board concluded that the use of guns in barbette batteries would be greatly modified in the future, and it recommended that the present carriages and platforms not be constructed in great numbers (Thompson 1979, pp. 81-82; U.S. Army Board of Engineers 1868).

(The last-mentioned carriages and platforms would be a heated topic of research and development. The Ordnance Department was then carrying out experiments on a wide variety of cannon and carriage designs, and one that showed particular potential was the "King's Depressing Carriage." This weapon was, in effect, a conventional muzzle-loading gun mounted on an inclined, sliding steel carriage. After firing, the cannon slid down and out of view for loading. Battery technology for the next half-dozen years revolved around the anticipated – but never implemented – introduction of the Depressing carriage.)

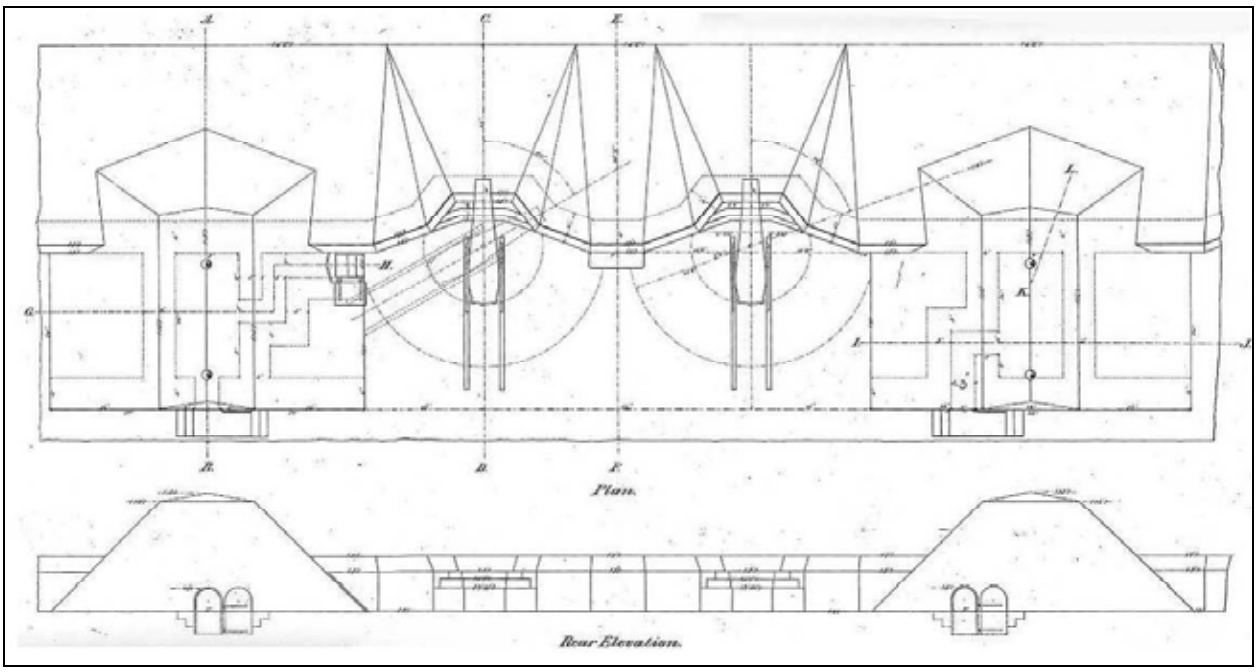

FIGURE 4 *Prototypical plan of an earthwork drawing: "Plans Sections and Elevations of a Barbette Battery as Proposed by the Board of Engineers for Fortifications," 1868 (NARA RG 77, Drawer 155, Sheet 14)*

These new American fortifications would be low-rise affairs, extending only 12 feet at most above grade when viewed from the sea. To provide maximum protection for the guns, the weapons would no longer be mounted in the long, unbroken lines of platforms built in the 1850s. It was now planned to emplace the cannon in pairs, and each pair would be separated by artificial earth hills called "traverses." Each traverse was also to house a powder magazine for ammunition storage. Brick-lined, arched tunnels through the earthworks permitted the safe movement of men and supplies during battles.

The new plans also called for a high degree of standardization of weaponry. Instead of the hodge-podge of calibers so common in pre-Civil War forts, the new batteries would mount only four different types of guns: 13-inch smoothbore mortars, 15-inch and 20-inch Rodman pattern smoothbore guns, and a 12-inch rifled Rodman gun still under development (Figure 5). (Neither of the latter two gun types, however, would ever proceed beyond the test phase.)(Martini 1999)

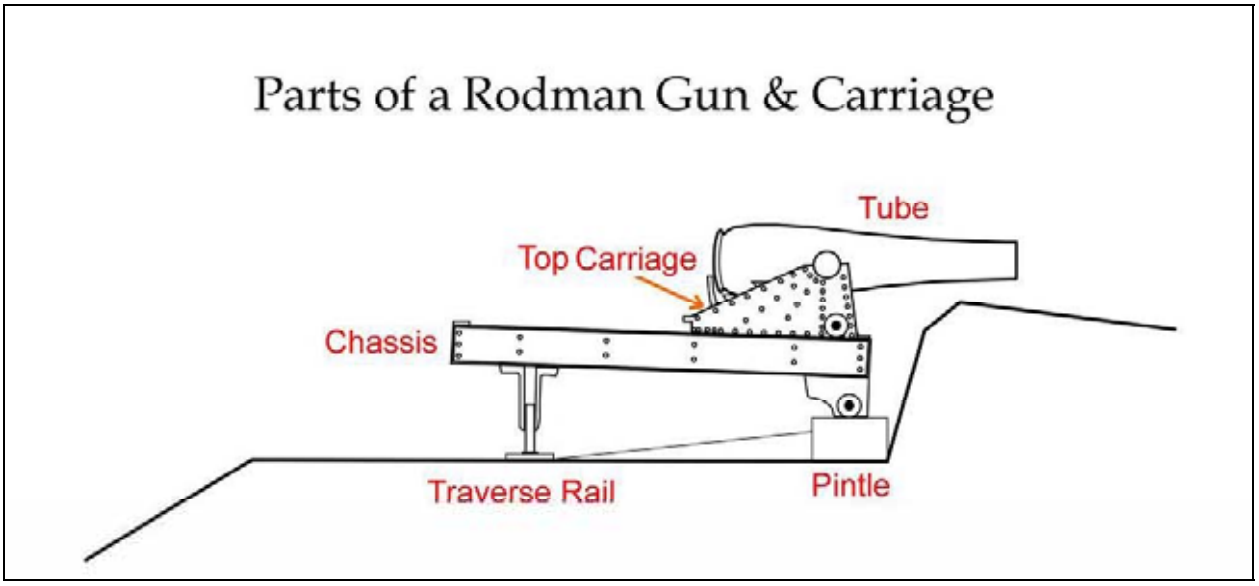

FIGURE 5 Parts of a Rodman Gun & Carriage

These batteries would be conspicuously similar in design, varying only slightly between forts due to local material availability and engineer preferences. Guns were to be emplaced entirely en barbette (i.e., mounted in the open), sitting atop simple wood or masonry firing platforms and aiming over a breast-high parapet wall directly in front of the gun (Figure 6). Set into this wall were brick steps for the gunners to use when loading powder and shell into the muzzle-loading Rodmans. Guns would be mounted in pairs, with a standard spacing of 34 feet between centerlines. Each pair of guns would be flanked by high earthen hills called "traverses," some measuring 20 feet tall, whose purpose was to prevent an enemy from being able to fire down the entire length of a gun battery (enfilading fire). And if by chance a gun were struck by enemy fire, the traverses on either side would restrict any damage to the two guns within the emplacement.

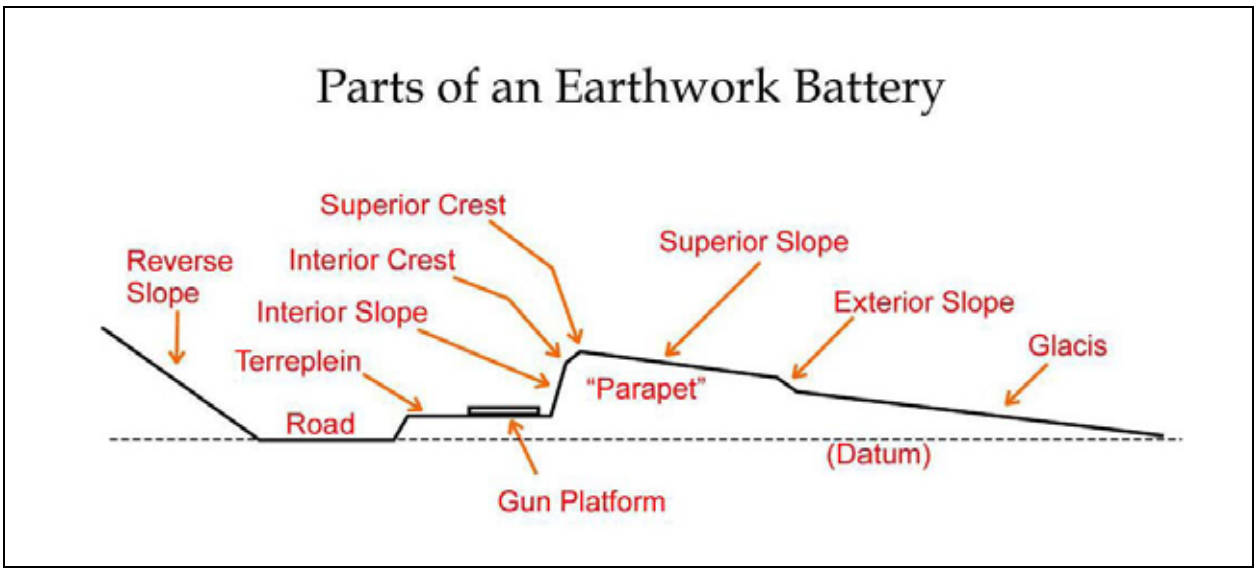

FIGURE 6 Section Through an Emplacement Showing Names of Architectural Features

Inside each traverse was service powder magazine for storing gunpowder for the battery (Figure 7). These service magazines were meant to provide ready-access for the gunners, while much larger "great magazines" located at dispersed locations held central reserves of propellant. Standard interior dimensions for a service magazine were to be 8' x 16', although exact dimensions, entrance locations, and arrangement of approach tunnels would vary. Shot (solid projectiles) and shell (hollow explosive rounds) would usually be stored outside on shot beds close to the guns themselves.

Historian Glen Williford (2005, pg. 4-5) described the flexibility and features of a typical "Plan of 1870" earthwork battery:

> These units could be strung together like beads on a string and lines or batteries could contain twenty or more gun emplacements. … In place of stone or brick, the plans incorporated the use of concrete – its first widespread application in American defenses.
>
> The principal material used for the parapet itself, any glacis in front, for the high traverse covers, and for any rear parados was sand, whose availability and cost advantage were obvious. Some 30 feet of earth or sand were specified for the depth of the terreplein. Magazines had hung wooden doors, and their interiors had special niches for oil lamps.

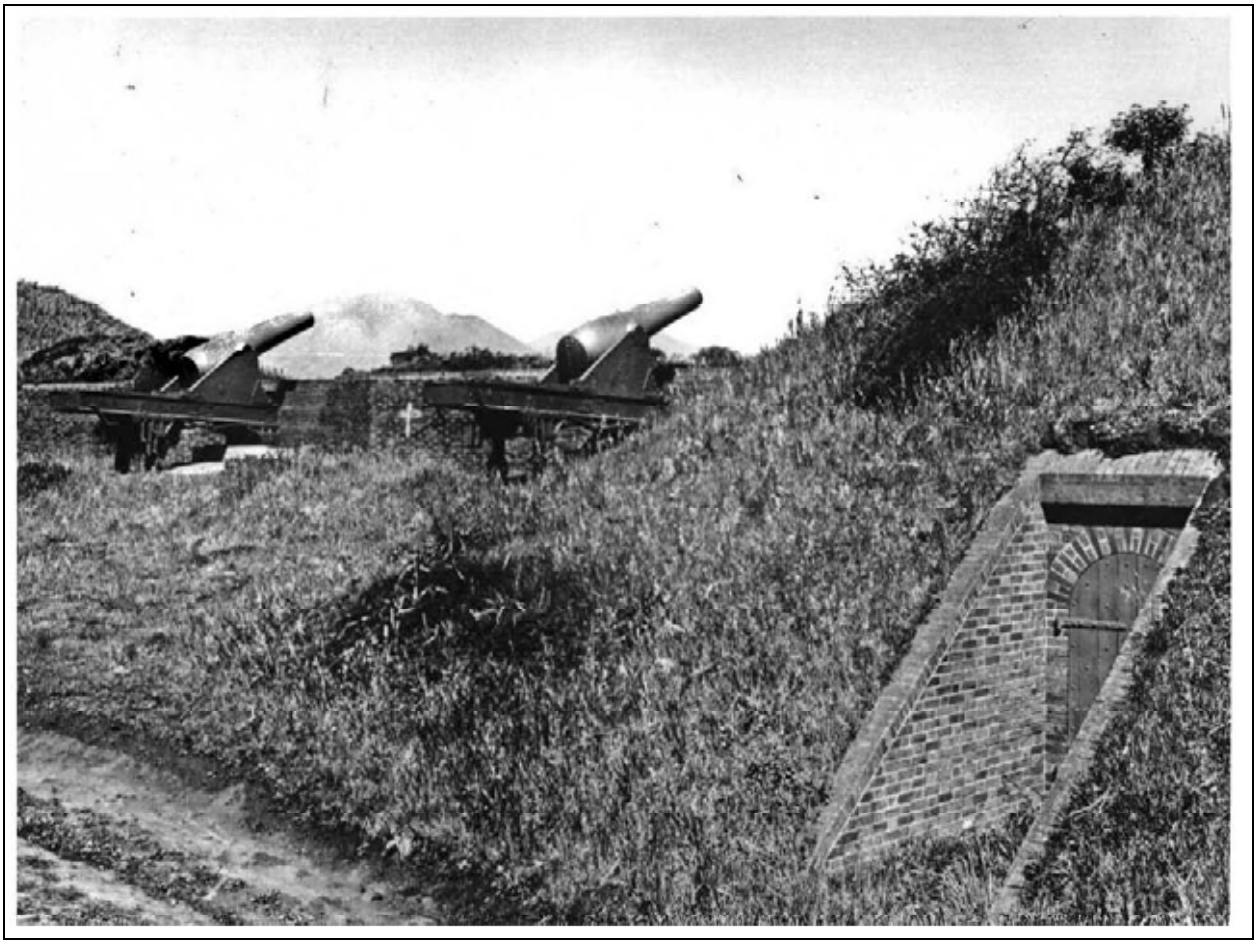

FIGURE 7 *A "Plan of 1870" two gun emplacement at East Battery, Fort Scott, c1910. Note the entrance to the service magazine at right. (GOGA, PARC, FOPO Collection.)*

Another feature of the Plan of 1870 works was the incorporation of mortars into the batteries (Figure 8). More than 100 13-inch caliber model 1861 mortars had been manufactured during the war, and it was felt their inclusion in the batteries and their plunging arcs of fire would be a perfect addition to the relatively flat trajectory fire of the Rodman cannon.

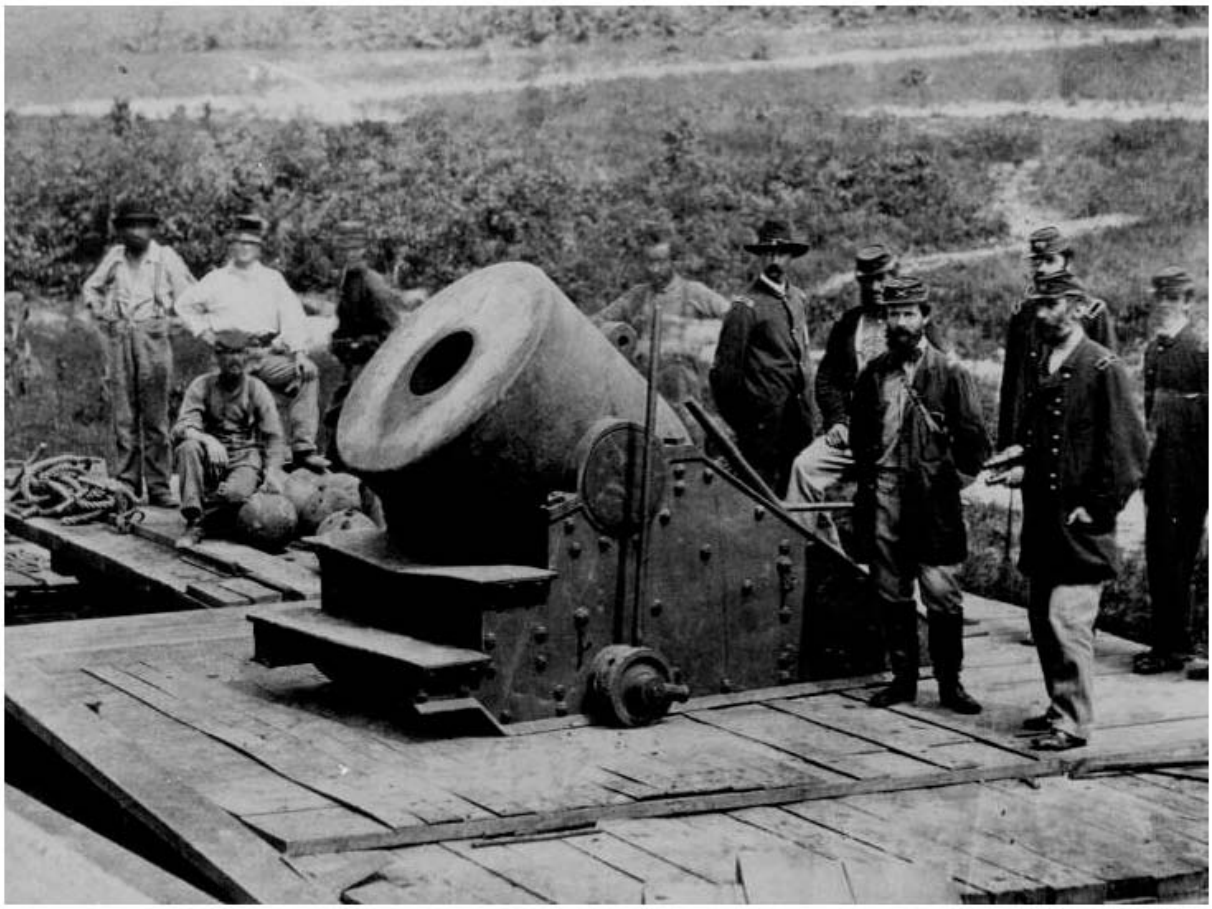

FIGURE 8 A Union 13-inch mortar Model 1861 installed during the siege of Petersburg, VA, in 1864. (NARA)

The drawback to the 13-inch mortar was its relatively short-range, slow rate of fire (weapons during this period were still aimed by brute force), and relative inaccuracy. A partial solution was to emplace mortars in groups; firing volleys of mortars at the same target greatly increased the probability of a hit. Two to four mortars per emplacement became the standard, with several mortar emplacements spaced along the length of a battery.

As opposed to the extensive masonry platforms required to support a 15-inch Rodman, mortar beds were relatively simple affairs constructed of overlapping courses of wood topped with iron skid plates. A mortar platform measured 13 feet square and 2 feet thick, and was set nearly flush with the ground. However, only three mortar emplacements around the country were ever armed before funding for the fortification program was cut off. None of these batteries were on the West Coast (Williford 2005, pp. 10-11). Numerous wooden mortar platforms were completed, though, and remained in place for decades afterwards (Figure 9). A cross-section of a related platform is depicted in Figure 10.

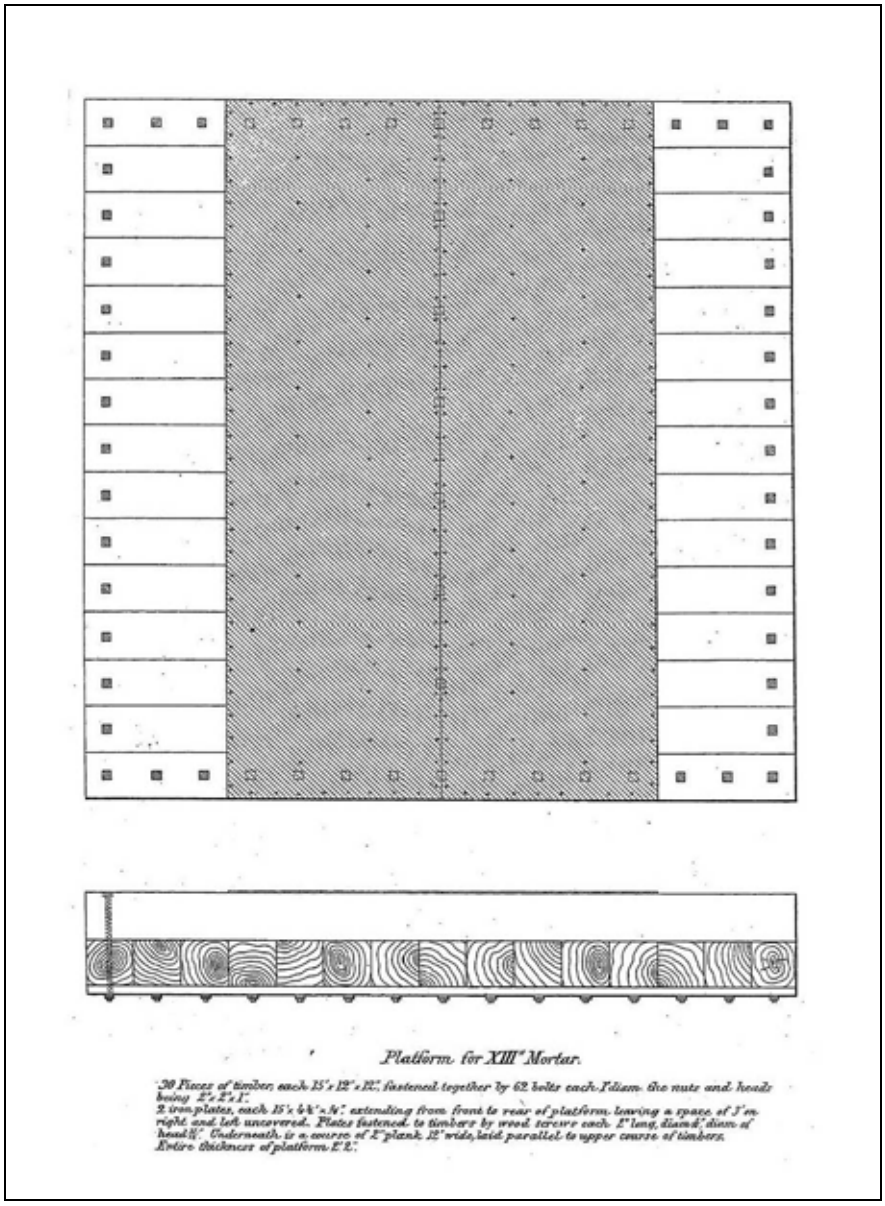

FIGURE 9 Platform for a 13-inch seacoast mortar, 1870, the type of platform installed at West Battery. (NARA, RG 77)

In 1870 the army established a special Pacific Coast Board of Engineers to oversee construction and modernization of the works around San Francisco Bay, where new batteries were proposed for Fort Point, Alcatraz Island, Angel Island, Lime Point in Marin County, and Point San Jose (Fort Mason) in San Francisco. At Fort Point the Board proposed to construct two lines of batteries on the hills behind the old masonry fort. These works would be named West Battery and East Battery, reflecting their geographic locations atop the bluffs west and east of the now-obsolete masonry fort.

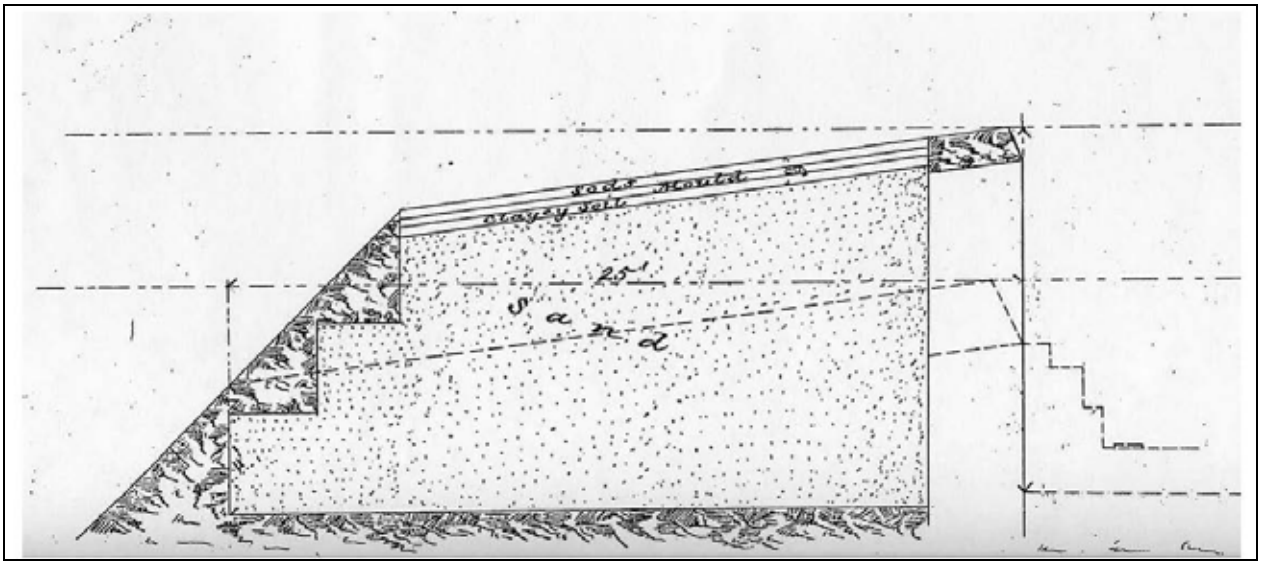

FIGURE 10 Detail from drawing titled "Cross-section of Parapets Shewing [sic]. Their Construction in Sand," 1871. Note the layers of sods, mould, and clayey soil on superior slope. (NARA, RG 77, Drawer 155, Sheet 17)

As work progressed on constructing the Plan of 1870 fortifications, financial and political realities began to rear their heads. The Congress began to question the army's continued expenditure of funds on what was becoming increasingly apparent as an obsolescent system of weapons, especially since international advances in weapons, warships, and tactics had left the old-pattern American smoothbore guns, no matter what their size, increasingly obsolescent. Rather than allocating money for modern armament and fortifications, Congress decided in 1876 to grant a mere $100,000 for "preservation and repair" of fortifications, and nothing for new construction. In 1877 things became even tighter when Congress adjourned without even passing an army appropriations bill.

For all intents and purposes, work on the Plan of 1870 ceased in 1876. Except for paltry amounts allocated for repair and preservation, no serious expenditures would occur until 1890. Again, Historian Lewis described the situation that followed:

> The deserted batteries were periodically inspected by caretakers, but neither funds nor labor was available to them for arresting the progressive deterioration that was to continue into the early 1890s. Third System forts, though patently outdated, and armed for the most part with smoothbore guns of Civil War or earlier vintage, continued to serve, of necessity, as major components of the nation's harbor defenses.
>
> This abortive program nevertheless marked a distinct turning point in American fortification practice, for the technical and tactical concepts on which it was based set a pattern that was to characterize all future harbor defense undertakings in the United States. … From this time on, a fort was a piece of real estate occupied by a number of dispersed individual batteries. Furthermore, the various items of armament intended for this project, though never in fact adopted, remained under constant development throughout the 1870s and 1880s, with the result that by about 1890 there became available greatly improved weapons around which was conceived the very advanced and extensive generation of defenses that followed (Lewis 1970, pg. 70).

In some ways, the lull in construction was a boon to U.S. Engineers. Instead of completing and arming the Plan of 1870 works, the army was compelled to wait until the early 1890s to begin construction on the next generation of defensive works, and during this period they were able to reap the windfall of technical developments in artillery and construction made by foreign powers.

During this period, numerous improvements were made that had a direct impact on America's next generation of harbor and coastal defense fortifications (Bearss 1973, pg. 286):

- Methods of manufacturing and rifling modern steel artillery pieces evolved to the point where breach-loading mechanisms could be introduced, thus allowing the use of highly efficient pointed projectiles and allowing for greater range and accuracy.
- The development of the "disappearing carriage" that utilized the recoil energy of a gun to lower itself behind a protective parapet for loading and aiming, without endangering the crew or exposing its location to the enemy
- The introduction of nitrocellulose- and nitroglycerin-based propellants that yielded higher muzzle velocities to effectively propel pointed projectiles.

In addition, military architecture had made great strides. Advances in concrete construction allowed the building of immensely strong battery structures that could withstand even direct hits by naval artillery. Mechanically operated hoists now lifted projectiles from subterranean magazines to surface gun emplacements, and embryonic telephonic and electrical systems were revolutionizing communications between various parts of the battery, the fort, and even the entire defensive area.

As Lewis summarized:

> Compared to the best of the smoothbore muzzle-loading cannon of the post Civil War period, the new weapons which began to emerge from the developmental stage around 1890 could fire projectiles that, caliber for caliber, were four times as heavy as to effective ranges two to three times as great; and they could do so with remarkably increased armor-penetration ability and accuracy (Lewis 1970, pg. 76).

In 1885, Secretary of War William Endicott convened a long-overdue board to review the state of the American defenses and make recommendations for upgrading the nation's forts. Their recommendations became the basis for the next generation of construction that would extend from 1890 to 1910, and give rise to the designation "Endicott Era" for these works. In 1886 the Board made its report, calling for extensive new fortification projects at 26 coastal locales. Recommendations ran from gun batteries to mortars to patrol boats and underwater minefields. Not all recommendations would be implemented, but the results would still bring sweeping changes to the coastal fortifications (Bearss 1973, pg. 287).

In general, the Endicott Board recommended emplacing several calibers of guns, each with its own anticipated targets, ranging in caliber from 12-inch rifles and mortars designed to deal with heavily armored ships such as battleships and cruisers, down to 3-inch rapid-fire guns meant to take on swift motor torpedo and patrol boats. In between these extremes were several other calibers of guns, each with its own justification for existence, although it is hard to see what the tactical difference might have been between a 5.7- and 6-inch guns. (Standardization would

come later.) In addition, electrically controlled underwater minefields would be planted in shipping channels and approaches.

Beginning in 1890, Congress began acting on the Board's report and resumed making annual appropriations for construction of coastal defenses. In 1890 and 1891, it passed acts authorizing almost $2 million in new construction. San Francisco and New York harbors were at the head of the list. Over the next several years, construction would proceed rapidly at these two ports that reflected their importance and the military's concern that they might be primary targets of enemy attack (Bearss 1973, pg. 288).

Work began in 1890 above Fort Point, where ground was broken for a 10-inch disappearing gun emplacement in Battery Marcus Miller. Before long, additional batteries were being constructed at the post (formally named Fort Winfield Scott in 1882) that mounted a variety of large caliber guns, rapid-fire weapons and mortars. The best location for many of these emplacements was the bluff occupied by West Battery, and by 1900 five different Endicott batteries had been built atop its earthworks (Figure 11). These new works removed or incorporated much of the 1870s emplacements, but a service magazines in truncated traverses survived to be incorporated into the new batteries.

The Endicott program would be succeeded by newer generations of coastal defense construction in the 20th century, but their stout emplacements would survive long after the guns were dismounted. In the Presidio, some of the 1890s emplacements would see military uses as late as the 1960s, frequently as storage facilities but sometimes as command posts and even soldiers' quarters during wartime (Figure 12).

2.3.2.2 Construction – Plan of 1870

The construction of earthwork batteries at Fort Point followed very closely the guidelines set forth in the 1868 report by the Board of Engineers. The most extensive retelling of the construction of West and East batteries is contained in *Historic Structure Report: Fort Point Historic Data Section*, prepared by historian Edwin C. Bearss of the NPS in 1973. This researcher has excerpted extensively the sections concerning West Battery taken from Bearss' landmark report. A copy of his report relating to the batteries' construction is included as an addendum to this report.[1]

Guided by the concepts contained in the Washington engineers' 1868 report on earthwork fortifications, the Pacific Coast Board of Engineers developed an extensive scheme of defense for San Francisco Bay. In their September 1870 report to the Chief of Engineers the members outlined their vision for works at Fort Point: "The best position on this shore for Barbette and Mortar Batteries to defend the approaches to the harbor were along the crest of the bluff, south of Fort Point, and that a powerful battery can be placed on the bluff East of the Fort."

The proposal was nothing if not expansive. In its original form, the Board envisioned West Battery as a series of gun and mortar positions to emplace 57 guns and 28 mortars, extending

[1] Wherever possible, primary sources Bearss cited in his Historic Structure Report will be used in this report.

along the ridgeline from directly behind Fort Point all the way to Telegraph Hill in the Presidio (today's Robb Hill). Its guns would face almost due west and command the approaches to the Golden Gate. Guns on its extreme right flank could also intersect with fire from batteries planned at Lime Point.

East Battery, by comparison, was a relatively small work consisting of only 16 guns and 4 mortars. It was positioned so that its field of fire was almost entirely within the bay, half of its guns oriented toward Alcatraz Island and the others facing toward Point San Jose.

Following closely the Washington Board's guidelines, the traverses would be spaced 64 feet apart on their centerlines, allowing enough room for two 15-inch Rodman guns in each battery. This spacing would also allow sufficient room to allow for any modifications in platform design or carriages that the Washington Board might later require. (At this time the army was still considering the adoption of the King's Depressing Carriage described earlier.) Far behind the batteries, earthwork positions for riflemen would be constructed near Robb Hill to prevent the artillery emplacements from being seized from the rear.

But the Pacific Board was also realistic about the eventual expense, stating the batteries would "probably absorb in their construction at the appropriations that will be made for defensive works at Fort Point for several years." They prioritized work on various sections of the batteries, with initial priority going to the northern half of West Battery, which would include positions for a 20-inch Rodman, fourteen 15-inch Rodmans, and eight 13-inch mortars. (The proposed 20-inch gun would later be replaced by another 15-inch Rodman.)[2]

A meticulously detailed map was also prepared that accompanied the report, showing the locations of the proposed works. In later years this plan would be followed with almost slavish accuracy as actual construction work took place, and today's surviving features of West Battery only vary by inches from measurements shown on the 1870 proposal.[3]

The Chief of Engineers had to concur, of course, and went along with the Board's proposal, although he felt the West Battery positions, "though unnecessarily high and too oblique in direction for the most efficient fire on hostile fleets running through mid-channel to enter the Golden Gate," were found to occupy the only available ground in the area. The southernmost of its guns near Telegraph Hill would actually be more than 2½ miles from mid-channel – almost the extreme range of a 15-inch Rodman. Consequently, Humphreys only approved constructing the northern portion of West Battery – the portion that survives today. With these reservations, Humphreys sent the Fort Point proposal to the Secretary of War, who approved the project on November 9, 1870, "subject to such changes in details by the Chief Engineer, as in the course of construction may be found advisable."[4]

Actual work on West Battery commenced in late December 1870, beginning with the six emplacements directly behind Fort Point. Initial projects included stockpiling of materials,

building and improving roads to the construction site, grading of the battery site, and excavation and embankment of earth for its terreplein and traverse.

Over the next several months, battery construction proceeded swiftly at Fort Point indicating the army's desire to have modern fortifications completed as soon as possible. Extensive correspondence in the National Archives indicates that works began at the northern end of West Battery and then proceeded in a southerly direction. By mid-April 1871 Stewart was able to report that work had progressed as far as the two mortar batteries, and that a portion of the traverse on the right flank of the battery had been embanked and excavations made for its magazine walls (today's Magazine 21). By May, the front, side, and end walls of the two mortar battery magazines had been raised to the spring lines of their arched interiors, and their parapets constructed.

Elsewhere along line of emplacements, work was in varying stages of progress on excavating, laying granite blocks and pouring concrete for gun platforms, constructing magazine walls, grading terrepleins, and sodding slopes. By June 30, 1871, the embankment of the terrepleins, traverses, etc. had been two-thirds completed for a length of 1,324 feet. Altogether 29,586 cubic yards of embankment had been positioned. Sodding totaled 7,180 yards. The breast-height wall had been begun, the masonry of two traverse magazines almost completed, and eight others about two-thirds finished. Foundations for 12 platforms and pintle blocks for mounting 15-inch Rodman guns had been put down. Altogether, 1,928 cubic yards of brick, stone, and concrete work were in place[5] (Figures 13 and 14).

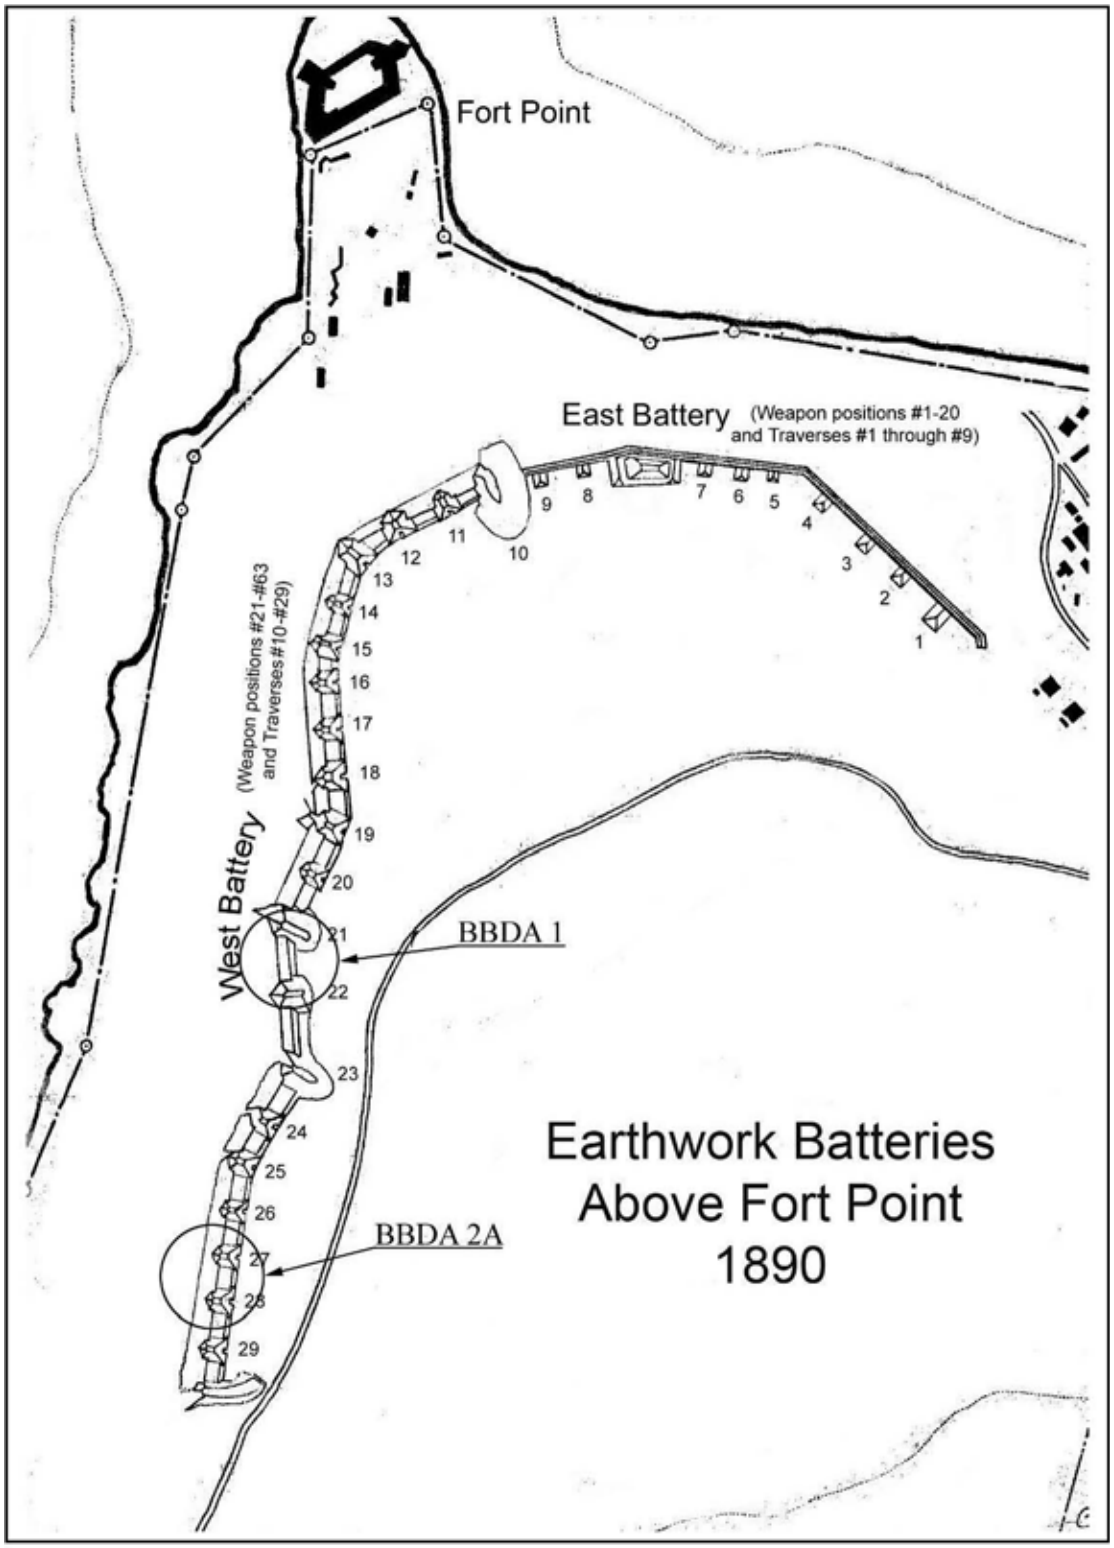

FIGURE 13 Extent of completed earthwork batteries above Fort Point in 1890. Current Remedial Action project areas are circled.

An unwelcome complication arose in early June when orders arrived from Washington directing that work on the batteries be suspended until decisions were made about how to arrange them to fit "King's counterpoise carriage."[6] This directive surprised the supervising engineer, Lt. Col. C. Seaforth Stewart, who had been proceeding with construction of standard barbette style emplacements, not depressing ones. He replied that the interior crests of the emplacements under construction at Fort Point varied in height from 180 to 196 feet above sea level, giving no tactical advantage to this style of embryonic disappearing gun.[7]

The situation was clarified in a couple of weeks when the Washington Board of Engineers made an updated report on the use of King's depressing carriage, and noted its inefficiency atop the Fort Point bluffs. "As it [West Battery] is quite exempt from enfilade fire and cannot be closely approached in front, it is believed that ordinary mounted barbette guns may be served with entire efficiency."[8] Work resumed in July.

Over the next year, work proceeded on the completion and partial arming of West Battery. Completing the magazines and emplacements occupied much of the workers' time, along with details such as sodding, grading, terracing, installing traverse rails, and hanging inner and outer magazine doors.[9] By Summer 1872, Stewart was readying West Battery for its armament and noted that to complete the process he wished to finish the rear slopes and to "unmask the fire" of several gun positions. This latter remark indicates that during construction, the terrain immediately in front of some of the guns had intentionally been left in its natural state, possibly to prevent prying eyes from seeing the work in progress. The cover now needed to be removed so the guns could have a field of fire.[10]

Plans for East Battery were finally approved in early 1873, and work commenced on that work shortly afterward. For the next year, work proceeded simultaneously on both East and West batteries. Although East Battery falls outside the immediate scope of this report, it should be noted that it differed from West Battery in one major feature: the presence of a covered way provided with a high earthen slope on the backside of the emplacement (a *parados*) that protected the road and battery from enfilade fire.

At East Battery, the engineers were given permission to elevate each pair of guns slightly from the adjacent pair. As the emplacements changed in elevation, they would "become better protected" from warships outside the Golden Gate, using the sloping topography of the hill west of the emplacements to form a parados.[11] The layout of East Battery and its sunken road – later buried – were documented in a 1934 aerial photograph showing early construction work on the Golden Gate Bridge (Figure 15).[12]

FIGURE 15 Aerial view of East Battery before construction of the Golden Gate Bridge toll plaza, showing the covered way and parados behind the emplacements. Battery Lancaster is at lower right. (Courtesy GGBHTD)

By contrast, West Battery did not have a covered way. While some–but not all–of its emplacements did have reverse slopes, these features varied in height from 2 feet to slightly more than 10. None formed a true parados, but could better be described as uneven road shoulders resulting from the undulating topography adjacent to the emplacements.

Numbers for the individual emplacements became standardized during construction of the two batteries. It should be noted that the terms West Battery and East Battery were never formally

[11] Board of Engineers, Pacific Coast to Humphreys, May 18, 1872, NARA, RG 77, Letters Received, Chief Engr.
[12] Photo GG 37, in GGBHTD collection.

designated military names but evolved out of common usage. To the army's constructing engineers, the fortification was simply one large earthwork. Correspondingly, they began numbering the emplacements at the extreme right flank of East Battery and numbered consecutively from east to west.

In its final form, East Battery consisted of 20 gun positions numbered #1 through #20 (including platforms for 4 mortars), and West Battery consisted of 43 positions numbered #21 through #63 (including platforms for 8 mortars).

For reference, Remedial Action Area BBDA 1 is located on the site of historic mortar emplacements #42-45, while the road portion of Remedial Action Area BBDA 2A is on the site of historic Rodman positions #58 and #59.

Col. Stewart reported that West Battery was "essentially completed" on June 30, 1873. The magazines could all be used (although not all the asphaltic floors had been laid); stone platforms, pintles, and traverse rails had been completed for 12 Rodmans; a ramp had been constructed between West Battery and East Battery; and 8 wooden platforms for 13-inch mortars had been constructed in the 2 mortar emplacements located midway along the line of batteries. In his annual report, Stewart noted that twelve 15-inch Rodmans had been emplaced, all of them in positions on the right flank of West Battery (Figure 16).[13]

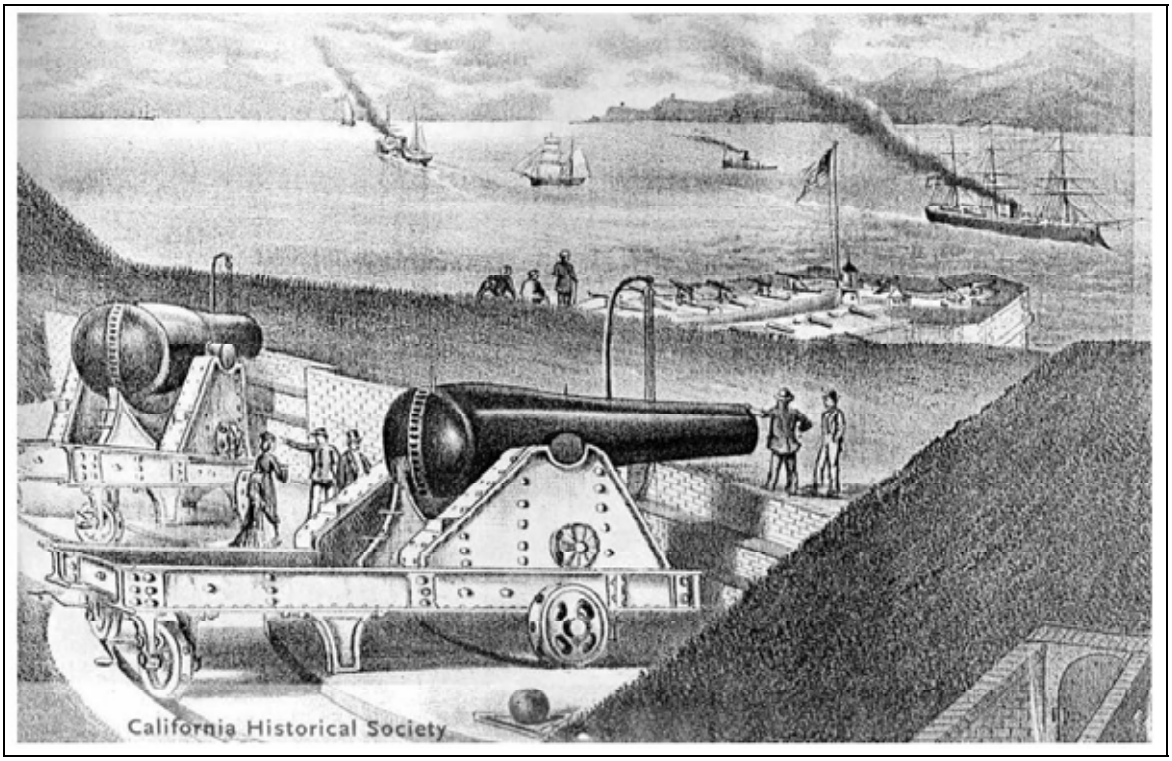

FIGURE 16 *A pair of 15-inch Rodmans in West Battery as portrayed in an 1877 issue of "The Wasp," a satirical San Francisco publication. The accompanying article berated the U.S. Government for wasting money on constructing obsolete fortifications. The artist took several liberties with perspective and location, since Fort Point is not visible at this angle from West Battery. Also, the fort is drawn backwards. (California Historical Society)*

[13] *Annual Report of Progress made in the Construction of Fort at Fort Point* in Fiscal Year 1873, NARA, RG 77, Letters Received, Chief Engineer. Positions occupied by Rodmans were Nos. 21-30, 36, and 37.

On May 18, 1874, the Rodmans in positions #21 through #32 were test fired for the first time. The targets were located at distances of from 1 to 2-3/4 miles distance, and the guns loaded with powder charges ranging from 60 to 100 lbs. When fired at elevations of 33 degrees the Rodmans and carriages performed perfectly, but when one 15-incher was intentionally fired at 0 degree elevation it recoiled violently against the end stops on its carriage. Although the iron chassis and carriage were slightly damaged, the emplacement itself took the shocks well and suffered only slight spalling of granite on the pintle block. The earthworks hadn't fared quite as well, though, and it was reported that the muzzle blast from the horizontal firing experiment had torn the sodding off the parapet.[14]

FIGURE 17 West Battery in 1880. (GOGA, PARC)

When Congress decided in Fiscal Year 1876 to reduce funding for harbor defenses, Fort Point was hit hard. Instead of the $80,000 requested, only $25,000 was allocated.[15] The result was an immediate changeover from construction to mere maintenance. Work was suspended on both batteries, and before even a single gun was ever emplaced in East Battery. The scene was grim for the supervising engineer, and would only get more frustrating. Historian Bearss summarized the sad entries from the annual reports for the following years:

"Congress for the next 14 years refused to vote funds for construction of seacoast fortifications, thus preventing completion of Battery East. With work suspended, the earthen batteries slowly deteriorated. Weasels and gophers burrowed into the traverses and parapets, and torrential rains caused some of the magazines to leak, with serious erosion wherever the works had not been sodded." (Bearss, p. 258)

Eventually, civilian "fort keepers" were employed with the paltry maintenance funds allocated the army, whose jobs included security, mowing earthworks, scraping rust, and painting ironwork. Sometimes they were assisted by soldiers from the regular garrisons of old Fort Point – that is, when the fort was occupied. One 1880s report stated that portions of the sodded slopes of the earthwork parapets and traverses (Figure 17) had recently been mowed, and observed how the sod consisted of "the thin and now matted roots of weeds and grasses," and without additional labor and expense for watering and weeding, it was impossible to keep the slopes "looking well during the long dry season."

Experience had shown the sod actually held up better *not* being mown when exposed to "the sun and strong steady winds of summer," and that the weeds and grasses acted as a mat, keeping the

[14] Stewart to Humphreys, May 21&27, 1874, NARA, RG 77, Letters Received, Chief Engineer.
[15] Humphreys to Steward, March 10, 1875, NA, RG 77, Letters Sent, Chief Engineer.

"light, dry soil, loosened and pulverized by the burrows of gophers . . . from being blown away." For this reason, considerable areas of the slopes were left unmowed.

Given the lack of funds for nearly 5 years, and all the hindrances to carrying out proper maintenance, Col. Stewart took a remarkably positive outlook when he reported the batteries looked "in tolerable good order."[16]

Periodically, the watchmen and the garrison were also able to perform maintenance on the non-earthwork portions of the batteries. These actions included clearing drains, painting doors, and painting and lacquering the ironwork on the wooden mortar platforms.

An 1882 inspection of the earthworks reported a variety of completed and incomplete emplacements. It also contained the notation that 12 timber platforms for heavy mortars had been laid in West and East Batteries, but that decay had set in. It also noted that ground had been prepared at the southern end of West Battery for 14 Rodman positions but no platforms had ever been constructed there.[17]

For some unknown reason, a test firing of the long-neglected 15-inch guns took place on October 1, 1884. The guns were manned and the targets selected: an offshore rock about halfway between Fort Scott and the Cliff House. After a couple of firings with reduced charges and only so-so accuracy (blamed on defective fuses), the colonel in charge ordered a gun loaded with a 450 lb solid shot and a full charge of 100 lbs of black powder. The results were predictable. The aging weapon recoiled along its chassis, which in turn buckled under the strain, allowing the 50,000-pound barrel and top carriage to jump completely off the chassis. The barrel dismounted itself and ended up splayed across the battery.[18]

In 1886, maintenance work ceased entirely for 2 years when Congress stopped all appropriations for preservation and protection of fortifications. When funds became available once again in 1888, workers cut brush and weeds around the earthworks, repaired sodding on slopes and broken ventilators, cleaned brickwork, painted magazine doors, and built steps over the earthen parapets. Iron plates from ten of the badly decayed mortar platforms were removed and stored in adjacent magazines.[19]

2.3.2.3 Endicott Era Construction

West Battery was perfectly sited to deal with an enemy approaching the Golden Gate, and for this strategic reason it was also selected as the site of the first Endicott batteries to be constructed in the San Francisco defenses. Work began on the new fortifications in June 1891 under the direction of Col. George Mendell of the Corps of Engineers (Figure 18).

[17] *Executive Documents of the House of Representatives for the 2nd Session of the 47th Congress, 1882–1883.* Washington: 1883, Serial 2092, Vol. 3, pp. 51-52.
[18] Stewart to Chief Engineer, October 2, 1884, NARA, RG 77, Letters Received, Chief Engineer.
[19] Col. George Mendell, Project Engineer, to Chief Engineer, July 7, 1890, NARA, RG 77, Letters Received, Chief Engineer.

By the end of the first month, Mendell's workers had dismounted four of the 15-inch guns in West Battery and begun demolishing their masonry platforms and other nearby emplacements. With the ordnance and earthworks gone, work next commenced on excavations for the disappearing gun emplacements. Progress was rapid and by December 1892 six of the new Endicott emplacements were nearly completed except for their armament. (These emplacements today comprise Batteries Marcus Miller and Godfrey.)[20]

Construction on another concrete emplacement in October 1896 required the removal of four more 15-inch Rodmans and their earthwork emplacements. (The site of today's Battery Lancaster position #3.) The guns were dismounted, their carriages and platforms salvaged, and the traverses and earthworks demolished.[21]

FIGURE 18 A 12-inch rifle in Battery Godfrey at the moment of firing, c1915. The brick entrance to Traverse #27, integrated into Godfrey's earthworks, is visible at lower left. (GOGA, PARC)

Then in June 1897, work began on two more emplacements (today's Battery Cranston) that necessitated removal of two more Rodmans, their carriages and platforms from West Battery. These were subsequently removed and their positions demolished. Only five 15-inch Rodmans remained in place: four in the extreme right end West Battery and one in East Battery. (The latter weapon–East Battery's first armament–had only recently been emplaced after being dismounted from West Battery.)[22]

[20] Mendell to Chief Engineer, September 1892, NARA, RG 77m, Letters Received, Chief Engineer.
[21] Lt. Charles L. Potter, Project Engineer, to Col. Charles R. Suter, District Engineer, 31 December 1896, SF Records Center, RG 77, Letters Sent by Project Engineer, Entry 1914.
[22] Potter to Suter, June 30, 1897, SF Records Center, RG 77, Letters Sent by Project Engineer, Entry 1914.

Work began in Summer 1898 on the last concrete emplacements that would require the removal of the armament from West Battery. These two disappearing gun positions (today's Lancaster #1 and #2) stood directly on the site of Rodman positions #21-24, and by the end of the year these last four smoothbore weapons had been removed to make way for new construction. With their removal, West Battery effectively ceased to exist.[23]

Battery East, although initially planned as the site for five more Endicott weapons, was left undisturbed. Although it had never been completed during the original "Plan of 1870" construction, it now mounted five weapons: a 15-inch Rodman in position #16 and four 8-inch converted Rodman rifles in positions #13, 14, 17, and 18 (Figure 19).

FIGURE 19 A pair of 8-inch rifled Rodmans and the covered way behind East Battery, 1915. The buildings of the Panama Pacific International Exposition can be seen in the distance. (GOGA, FOPO Coll)

The last Endicott fortification constructed at West Battery was Battery Boutelle, an emplacement for three 5-inch guns on balanced pillar mounts. No armament had to be removed to make way for the new work, since the 13-inch mortars intended for the site had never been mounted. Even their wooden platforms had been removed sometime prior to 1898.[24] When designing Boutelle,

[23] Lt. Louis C. Wolf, Project Engineer, to Maj. Charles E.L.B. Davis, District Engineer, December 31, 1898, SF Records Center, RG 77, Letters Sent by Project Engineer, Entry 1914.
[24] Drawing "Armament Sketches of Defensive Works in San Francisco Harbor," January 1, 1898, GOGA, PARC, FOPO Collection.

the engineers took advantage of pre-existing earthworks on the site by nestling the new emplacements snugly between traverses #22 and #23. Work on the battery began in 1898 and was completed in 1901. During the course of construction, the decision was made to retain the magazine in Traverse #22 and incorporate it into the new battery, where it apparently served as an auxiliary ammunition storage room for the battery's 5-inch fixed ammunition under the designation "old magazine."[25]

Retelling all the details of construction of the Endicott batteries falls outside the scope of this report, but the following summary provides an outline of their origins. Starting at the northern end of the line and working south, they are:

Name	Armament	Commenced	Completed
Battery Lancaster	Three 12-inch rifles on disappearing carriages	1896	1900
Battery Cranston	Two 10-inch rifles on disappearing carriages	1897	1898
Battery Marcus Miller	Three 10-inch rifles on disappearing carriages	1891	1898
Battery Boutelle	Three 5-inch rifles on Balanced Pillar mounts	1898	1901
Battery Godfrey	Three 12-inch rifles on barbette mounts	1892	1896

2.3.2.4 Alterations and Later Uses

Following its disarming, only a few traces of Battery West remained, including six traverses and magazines (#s 21, 22, 23, 27, 28, and 29), a four-gun mortar pit (positions #s 42-45), and the partial outlines of two unfinished two-gun Rodman emplacements at the southern end of the line (positions #s 60-63). One of these magazines (#23) was physically incorporated into the structure of Battery Godfrey and became a storeroom off the battery's generator room. The other surviving magazines remained as distinct structures with their own entrances, and show up on period maps and drawings simply labeled "magazine." The rooms' exact uses are unknown, but they probably served as simple storage spaces for the adjacent Endicott batteries.

The history of the Endicott batteries surrounding the Golden Gate is documented extensively in historian Erwin Thompson's *Historic Resource Study: Seacoast Fortifications of San Francisco Harbor*, prepared for the NPS in May 1979. For the batteries along the former alignment of West Battery, their history was relatively short. By 1918 the batteries were recognized to have several faults: all were located too far inside the Golden Gate straits to have effective fields of fire; their carriage designs prohibited the barrels from being elevated for maximum range; and they were of an obsolescent design. Within a few years of their completion, the batteries' defensive roles were replaced by forts that had better fields of fire and were located further to the west – and closer to any potential enemy – posts such as Fort Miley in San Francisco and Fort Barry in Marin County.

Battery Boutelle was the first to be disarmed in 1918 when its 5-inch guns were removed for field use in Europe. Battery Cranston was disarmed that same year, and Marcus Miller's guns were removed in 1920. Batteries Cranston and Godfrey both retained their guns through World War II, but apparently more as a matter of neglect than for any tactical purposes. They finally

[25] "Report of Completed Works, Form 7, Battery Boutelle," corrected to December 1919.

lost their armament in 1943 during a general scrapping of 10-inch and 12-inch Endicott weapons remaining in the Bay's defenses.

Alterations to 1870s Traverses

The earthen traverses covering these magazines also survived, but four of the six were truncated by several feet to lower their profiles when viewed from the sea. When originally constructing the earthworks, the engineers seemingly gave little thought to making West Battery inconspicuous. Historic photographs taken from the bay reveal that the battery's traverses stood out against the sky as a series of tall, trapezoidal shaped mounds stair-stepped along the Fort Point hillside. The battery was so pronounced that its earthworks and guns were even visible from Pacific Heights (Figures 20 and 21).

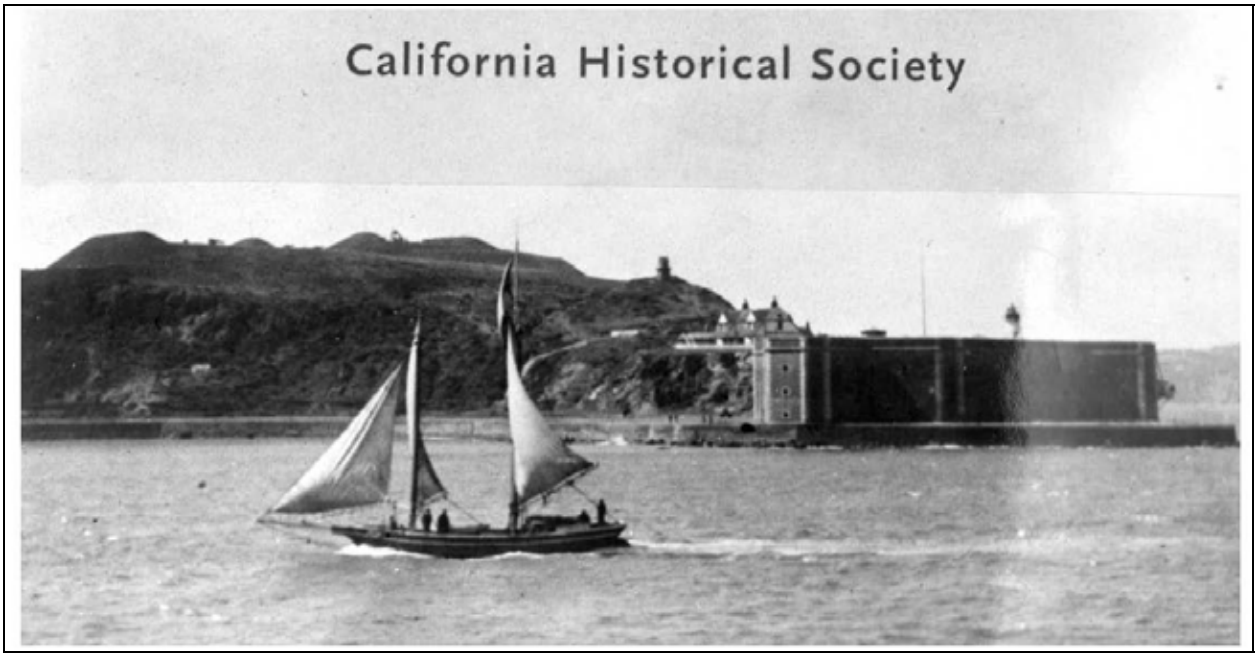

FIGURE 20 Fort Point and a portion of West Battery as viewed from the bay, c1890. Note the 15-inch Rodmans mounted between the traverses. (California Historical Society)

FIGURE 21 *The traverses of West Battery appeared like a serrated edge in this view from Broadway and Lyon Streets in Pacific Heights. A portion of the Presidio's main post is in the foreground. (California Historical Society)*

By contrast, the army wanted to draw as little attention as possible to the presence of the Endicott batteries, not so much for secrecy but rather to deny enemy gunners a good target. The traverses from the 1870s that still remained adjacent to the newer works would have only served to draw attention to the fortifications' locations.

In his 1920 treatise Notes on Seacoast Fortification Construction, Colonel Eben E. Winslow of the U.S. Army's Corps of Engineers described the evolving theory of coastal fortification design in the late 19th century:

> In the earthen emplacements constructed during and just after the Civil War, the guns were mounted on barbette carriages and were, therefore, always visible. In order to obtain a sufficient volume of fire they were mounted fairly close together along a parapet, although it was customary, wherever infilade [sic] fire was feared, to place frequent traverses in the line of guns so as to reduce the effect of this enfilade fire. In general, the guns were emplaced in pairs, two guns in the interval between two traverses.
>
> These traverses extended high above the parapet and, in fact, above the guns and, therefore, were visible from a considerable distance. The guns then in use were mounted in barbette and were always exposed to view, the ranges used at the time were comparatively short, and since the guns themselves were not concealed no concealment was lost by the exposure of the traverses to view.
>
> When, however, the disappearing [gun] principle was introduced into seacoast gun carriages so that the gun in the loading position was entirely out of sight, it became desirable to conceal, if possible, the position of the gun. It appeared to be desirable to reduce the height of the traverse to that of the parapet, so that when seen from the front, the emplacement appeared with an unbroken horizontal crest, no guns being visible and no traverses indicating the approximate positions of the guns. The early

designs for disappearing emplacements as prepared by the Board of Engineers were all based on this idea (Winslow 1920, pp. 109-110).

During the construction of the Endicott batteries, the tall earthwork traverses of West Battery were reduced in height to correspond to the adjacent parapets and superior slopes of the new concrete fortifications. Although the engineers' reports for the concrete fortifications at Fort Scott make no specific reference to lowering the old traverses, it was likely done in accordance with the new design standard described by Winslow as "an unbroken horizontal crest … and no traverses indicating the approximate locations of the guns" (Figure 22).

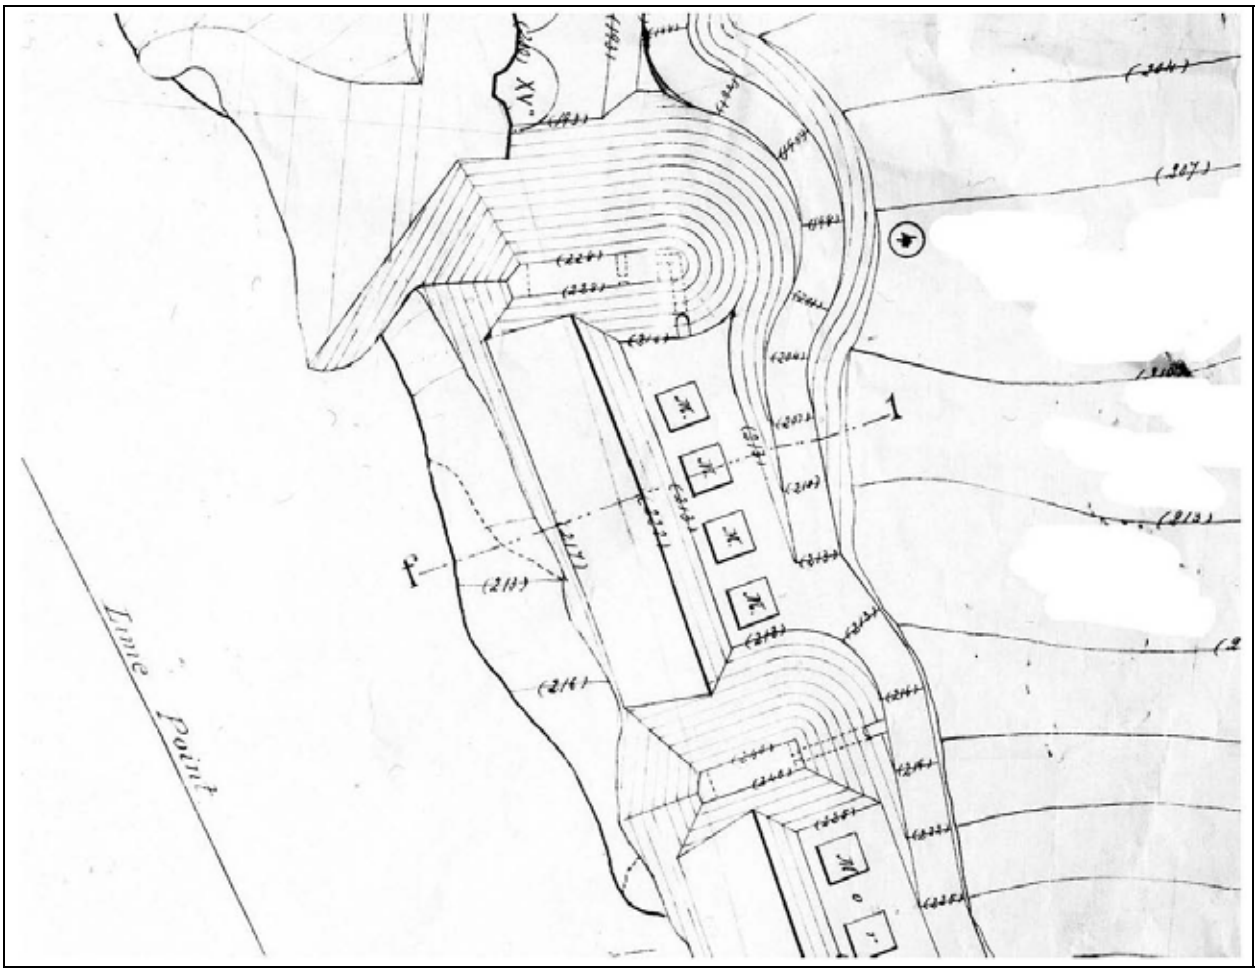

FIGURE 22 Section of original 1870 engineer plan showing Traverses 21 (top) and 22 (bottom) and positions for 13-inch mortars. Remedial Site BBDA 1. (NARA RG 77, Drawer 94, Sheet 102)

The best-documented example of reducing a traverse's profile is Traverse #21 on the right flank of the mortar battery and adjacent to Battery Marcus Miller. The original 1870 map (Figure 22) shows a proposed crest of 228 feet for this traverse, while an 1891 drawing shows the finished elevation as 229 feet. (Discrepancies of about a foot are common to historic maps of the area.) By 1902, however, 7 feet of the traverse had been shaved off and its elevation reduced to 222 feet, bringing its crest to the same level as the superior crest of the adjacent mortar emplacement.

Although leaving the magazine with only about 2 feet of earthen cover, the traverse was now much less conspicuous. Viewed from the water, the battery now appeared more like a simple earthen bank in the hill (Figure 23).[26]

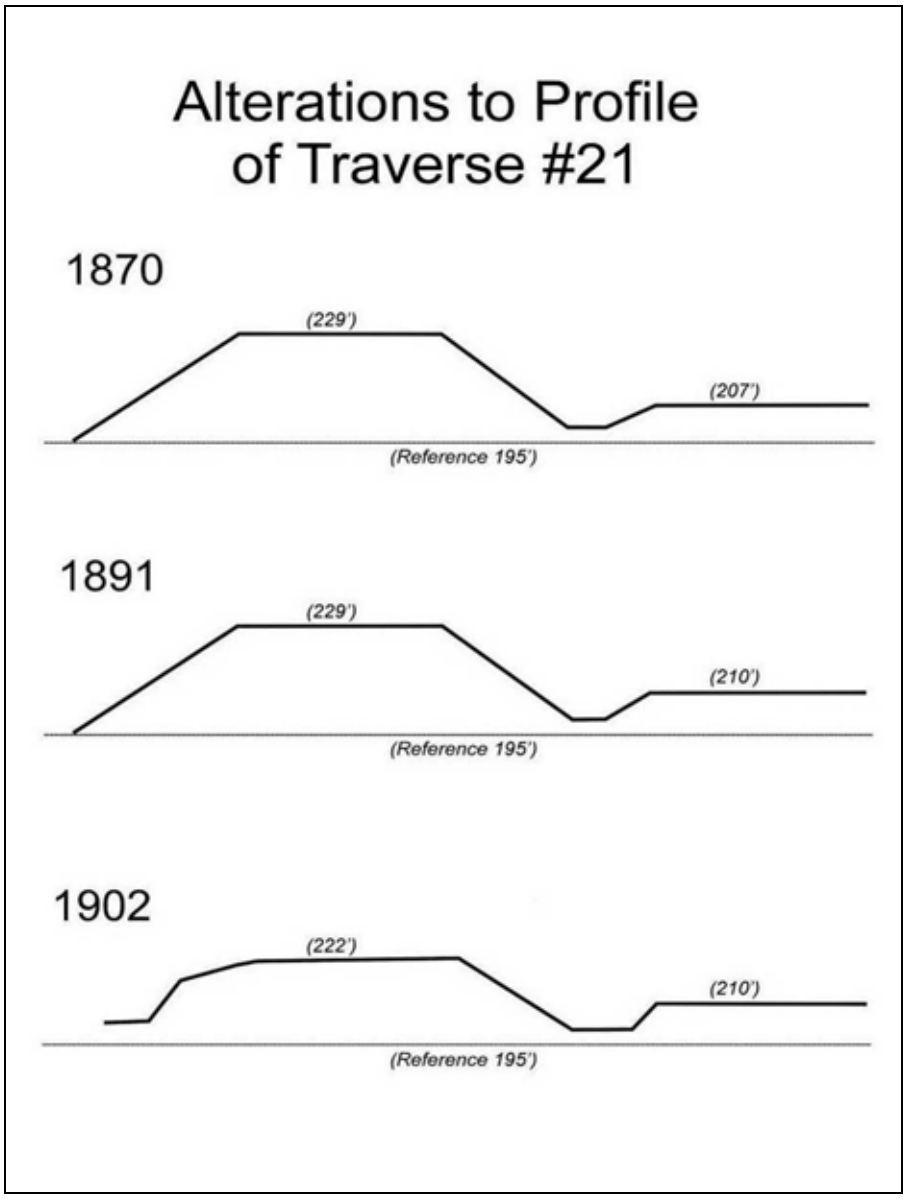

FIGURE 23 *Three views of Traverse 21, view north. Note also the change in road width and the 3-foot height increase of the open area behind the battery.*

The same recontouring efforts occurred at Traverse #27 on the left flank of Battery Godfrey, which was reduced in height from an original elevation of 274 feet to a post-Endicott elevation

[26] Drawing "Plan and Sections of Batteries for Fort Point" 1870. (GOGA, PARC, FOPO Collection; NARA RG 77, Drawer 94, Sheet 102); Drawing: "Gun Emplacements No 12–13 for 10 in. guns at Fort Point etc" 1891. (PARC, GOGA, Drawer 27, Folder 2; NARA RG 77, Drawer 94, Sheet 110-1); "Battery Commander Station for Battery Cranston," August 12, 1902. (GOGA, PARC, Drawer 272, Folder 4; NARA RG 77, Drawer 94, Sheet 110-12).

of approximately 270 feet.[27] Based on visual inspections, similar reductions in height appear also to have taken place at Traverses #28 & 29. (Confirming measurements have not yet been made.)

By contrast, Traverses #22 and #23 seem to have retained their original contours, although their crests are now suffering from erosion caused by visitors scrambling across the batteries. In fact, the footprint of Traverse #22 is somewhat larger than when first constructed, probably due to additional fill being placed around its eastern and southern sides when Battery Boutelle was constructed. As a result of this additional fill, a 25-foot extension had to be added to the corridor leading to the traverse magazine inside.[28]

2.3.2.5 Alternations to 1870s Gun Emplacements

Mortar Battery

The four mortar positions located between Batteries Marcus Miller and Boutelle lasted well into the 20th century, along with the traverses flanking both sides of their emplacement. Subsequent alterations and filling can be traced through historic drawings made of the battery, beginning with a section from the original 1870 engineer map for the Fort Point batteries. This map shows the relationship among the original slopes, the mortar platforms, road, reverse slope, and "natural surface." (Figure 24)

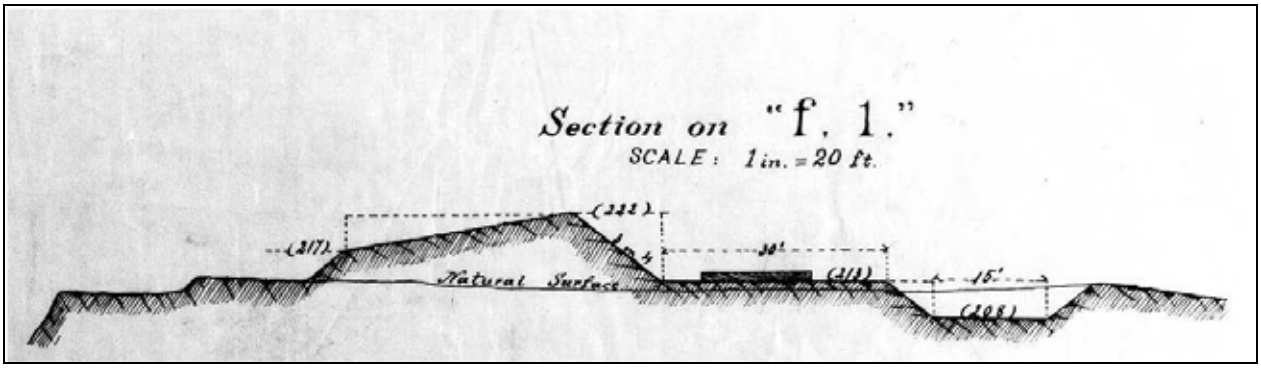

FIGURE 24 Section "f, 1" through mortar positions, showing original height of road cut behind emplacement. (NARA RG 77, Drawer 94, Sheet 102)

A map prepared in 1902 showing a proposed (but never implemented) extension of the Endicott batteries onto the mortar site revealed that the original outline of the earthwork emplacement was still recognizable, complete with the interior slope and intact (albeit truncated) earthen traverse and magazine #21 on the right flank (Figure 25). The four wooden platforms were gone, but the open area where they had been located was still plainly discernible.[29]

[27] Drawing "Plan and Sections of Batteries for Fort Point" 1870; "Report of Completed Works, Form 7, Battery Godfrey," corrected to 1919.
[28] "Report of Completed Works, Form 7, Battery Boutelle," corrected to December 1919.
[29] Drawing "Battery Commander Station for Battery Cranston," August 12, 1902. (GOGA, PARC, Drawer 272, Folder 4; NARA RG 77, Drawer 94, Sheet 110-12).

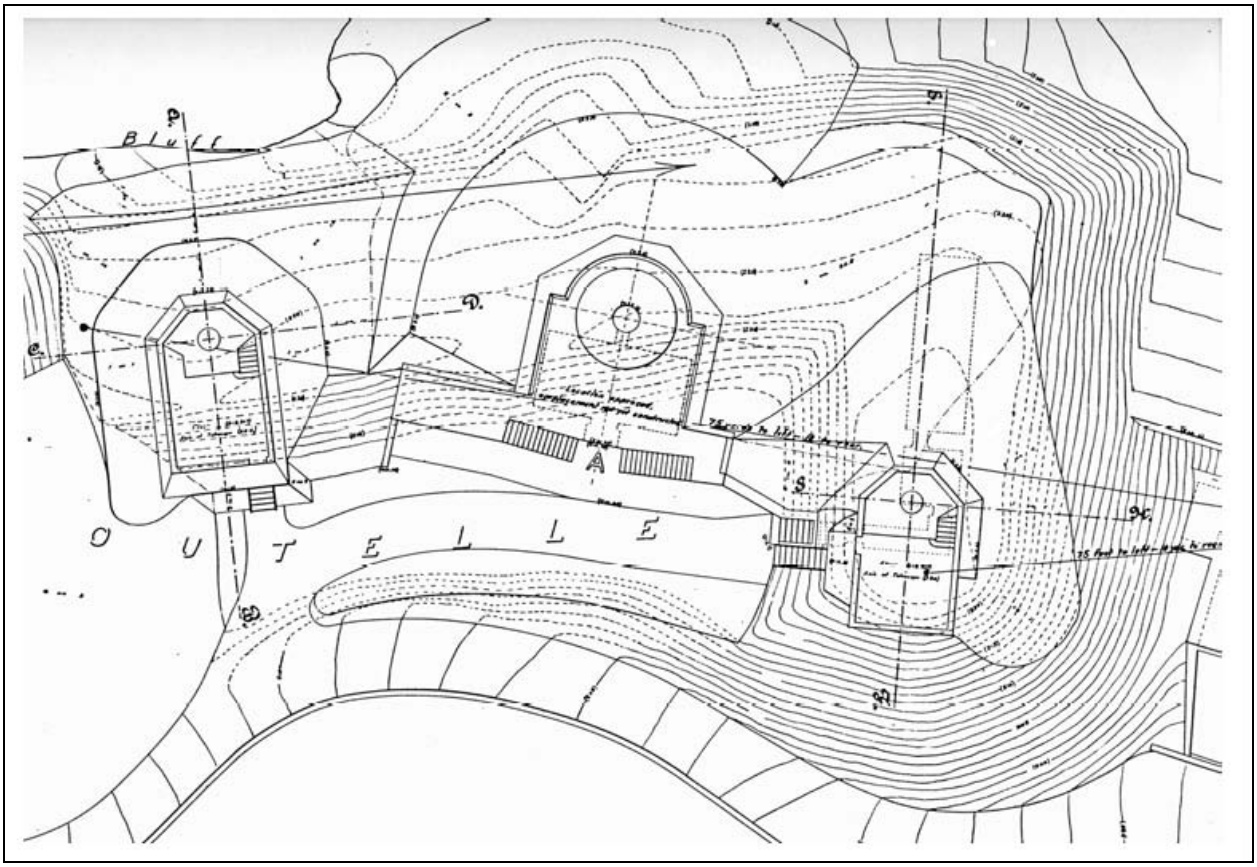

FIGURE 25 The outlines of Traverse 21, its magazine, and the former mortar battery location are visible as dotted lines in this 1902 proposal for an extension of Boutelle. Remedial Site BBDA 1. (PARC, GOGA)

At some undetermined date, the superior slope of the old mortar battery was flattened and a disposal site established on its site. This dump was likely associated either with the garrison buildings at nearby Fort Winfield Scott or with a sprawling complex of World War I temporary barracks erected behind the batteries in 1917. Initially, debris appears to have been simply dumped down the face of the cliff leading to Baker Beach. In 1922, a concrete and brick trash incinerator was built on the flattened area (Figure 26). Designated as Fort Scott Building #237, it measured 6'4" x 8' and cost $414 to construct. It was arranged on a general east-west alignment across the former superior slope.

In 1934, the original incinerator was replaced by a newer version built primarily of concrete. It measured 9' x 13' and cost $800. Based on historic photos, this new incinerator was located on the northern side of the dump area, and was oriented on a roughly north-south alignment. To make room for this structure, yet another portion of the 1870s superior slope had to be cut away. The 1934 photograph also shows what appears to be a flat paved area directly in front of the incinerator possibly made of poured concrete that allowed vehicles to pull directly up to the furnace doors. Unfortunately, the extent and exact composition of this paving feature is not known (Figures 27, 28 and 29).

FIGURE 26 1922 incinerator on dumpsite. View looking south. Remedial site BBDA 1. (GOGA, PARC)

FIGURE 27 1934 incinerator. View north. Note excavation into earthworks at right. Remedial site BBDA 1. (GOGA, PARC)

Photographs in the collection of the Golden Gate Bridge District show that dumping activities continued at the site at least through 1967. In that year, a large expansion of the disposal site was recorded. (Figure 30) This material in the photo covers not only the slope below the dumpsite but also fills the flattened dump area on the former superior slope of the mortar battery.[30]

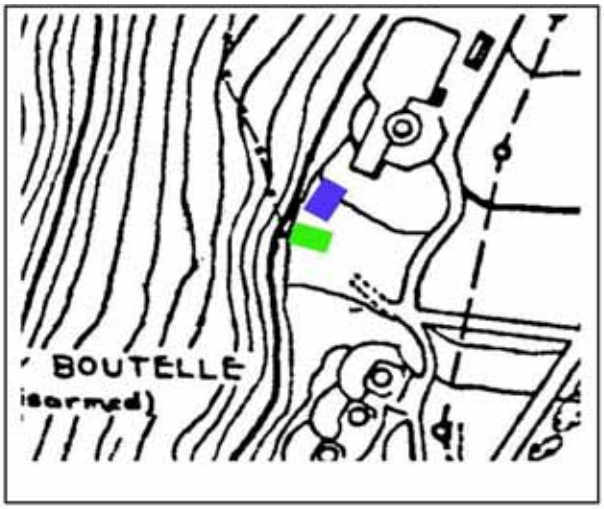

FIGURE 28 Approximate locations of two incinerators: 1922 (lower) and 1934 (upper)

A pond of water has apparently formed directly over the dumpsite. The curved outlines of the traverses flanking the former battery are still visible. Remedial Site BBDA 1. (Courtesy GGBHTD)

Rodman Emplacements

As noted in the 1882 inspection of West Battery, the last 14 Rodman positions were never completed. An 1898 plan of the Fort Point batteries confirms that construction work on the positions had only extended to completion of the magazines and traverses, and grading of the parapets, superior slopes, and glacis. No work was ever carried out on the masonry of the parapet walls lining the interior slopes, the firing steps, or gun platforms. The 1898 plan also reveals that a never-constructed traverse and magazine were planned for the southern end of the line, and would have become Traverse #30.[31] Whether or not any grading for this traverse had been completed is unclear. (The same map showed that three of the wooden platforms had been removed from the mortar battery between Traverses #21 and #22, and that a fourth remained in place but was "unserviceable.")

[31] Drawing "Armament Sketches of Defensive Works in San Francisco Harbor," January 1, 1898, GOGA, PARC, FOPO Collection.

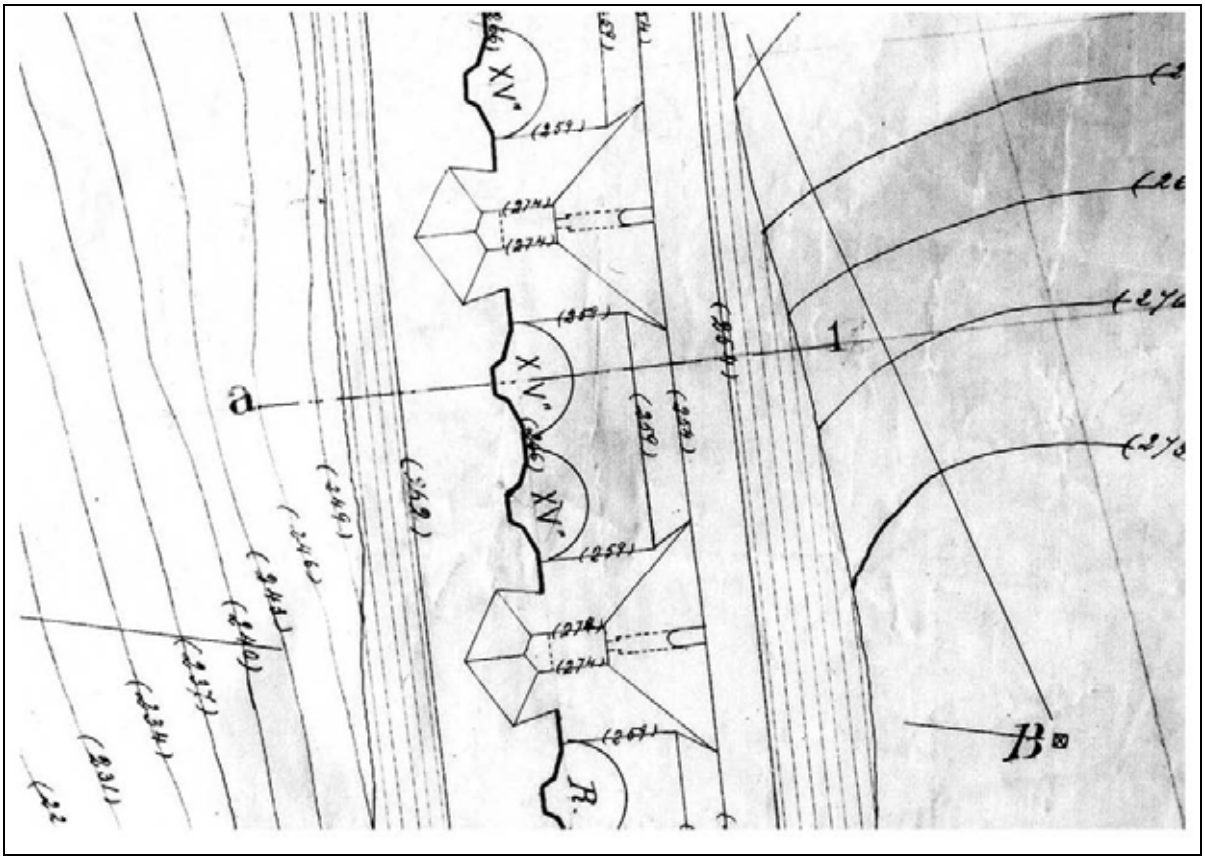

FIGURE 31 Section of original 1870 engineer plan showing Traverses 27 (top) and 28 (bottom), and Rodman positions #58 and #59. Section a – 1 is the site of the present overlook access road. Remedial Site BBDA 2A. (NARA RG 77, Drawer 94, Sheet 102)

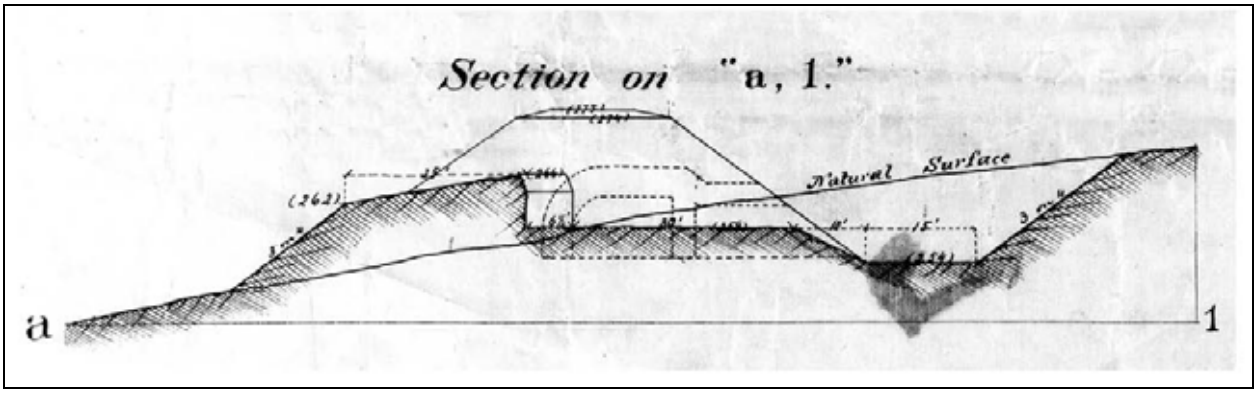

FIGURE 32 Section "a, 1" through Rodman positions #58 and #59, showing deep road cut (now filled) behind emplacement. (NARA RG 77, Drawer 94, Sheet 102)

When Battery Godfrey was constructed beginning in 1891, gun positions #50 through 57 were demolished along with Traverses #24 through 26. Traverse #27 was incorporated into the left flank of Godfrey. Gun positions #58 and 59 (Figures 31 and 32 above) were buried at this time and the road cut behind the emplacement filled by a high bank of earth. This bank, measuring approximately 8 feet high, formed a parados at the southern end of the battery that prevented enfilade fire from ships entering the Golden Gate. This embankment was converted into a service road leading to a dump constructed on the forward slope of Battery Godfrey sometime around 1940.

FIGURE 33 The three 1870s traverses on the left flank of Battery Godfrey are visible in this February 1942 view. The curved landform between #27 and #28 is a parados constructed to protect the left flank of Godfrey. Tire tracks probably indicate dump activities on the forward slope. Remedial site BBDA 2A. (PARC, GOGA, Cooper Collecton)

A detailed survey of the topography of the dump area was prepared by the 663rd Engineer Topographic Company in July 1954. It showed the general area of the dump, access roads, and proposed locations for new salvage shop and reclamation bins. It also showed that the reference elevation for the dump access road across the former Rodman positions was 262 feet, and the elevation of the surviving historic road behind the traverses was 255 feet – a difference of only 1 foot from the 1870 road elevation.[32]

This filling episode also explains why the entrance door to Traverse #27 (Figure 33 above) is located so far below current grade; the magazine lintel is at the historic road level while the adjacent service roads leading to Battery Godfrey and the 1940s dump are built atop 7 to 8 feet of fill that formed the 1890s parados.

Today this road over the Rodman positions serves as the unpaved access road to the Fort Scott Overlook, and is designated remedial site BBDA 2A.

Alterations to Superior Slopes

As part of the construction of the Endicott batteries, the area immediately in front of each gun emplacement (the superior slope) was cleared and graded to give the weapon a clear field of fire

[32] Drawing "Special Map for Redesign of Salvage & Dump Area Zone 1300," July 1954. Prepared by the 663rd Engineer Topographic Co., U.S. Army, Office of the District Engineer, San Francisco. PARC, GOGA, Drawer 275, Folder 2.

towards the Golden Gate. Each slope had a downward angle of this slope based on the lowest declination the gun barrel could be depressed below horizontal. In a major-caliber battery, the portions of the superior slope closest to the gun were constructed of concrete. At a distance from the muzzle, however, the material changed to graded and sodded earth. To prevent the weapon's powerful muzzle blast from tearing up the earthen slope, a thin concrete extension called a "blast apron" was frequently added to the concrete superior slope – usually based on experience with the gun's particular firing characteristics.

Figure 34 shows both the masonry and earthen superior slopes that were incorporated into Battery Marcus Miller's design.

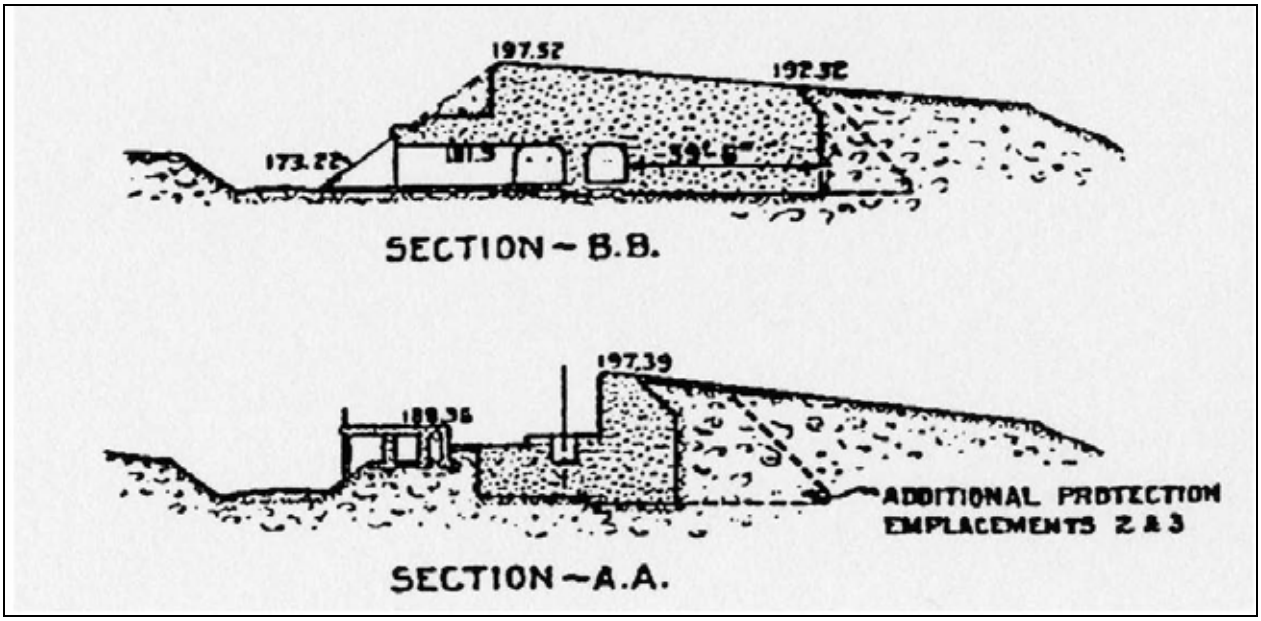

FIGURE 34 Sections through two portions of Battery Marcus Miller. Note the impressive thickness of the concrete in front of the magazines (upper). (Report of Completed Works, Form 7, Marcus Miller)

Due to the increasing elevations of the batteries south of Fort Point, each emplacement's superior slope ended up at a slightly different elevation from the adjacent battery. These differing slope heights created a visibly terraced, or "stair stepped," landscape when viewed from the ocean (Figure 35).

When the batteries were active defensive installations, these superior slopes were kept totally free of trees and any large vegetation that might obscure the field of fire. As time progressed and the guns became obsolete, though, the army ignored the superior slopes and their once-clean grades and profiles were eventually softened by vegetation spread and erosion. Portions of the graded slopes and terraces are still known to exist beneath the brush and tree cover that grows in

the area today, and are periodically exposed to view when the park carries out vegetation removal clearing projects.[33]

FIGURE 35 The terraced superior slopes of Endicott era batteries are visible above Fort Point in this view taken c1900. A 12-inch disappearing rifle at Battery Lancaster appears at left. (California Historical Society)

2.3.2.6 Filling Activities Adjacent to Batteries

The access road paralleling the line of Fort Scott batteries has its origins in the original service road constructed in the early 1870s to serve the gun emplacements at West Battery. Over the years, this road has frequently been referred to as a "covered way," based on the assumption that the road was constructed with high sides to protect it from enemy fire.

Actually, the road was not originally constructed as a feature sunken below ground level. When first constructed the road's level was roughly at the same elevation as the surrounding landscape. This landscape, however, has been raised over the decades as a result of grading activities associated with the Endicott fortifications and other construction events.

The earliest map of the West Battery road indicates that the height of the outboard shoulder (i.e., the side away from the gun positions) varied from exactly ground level to a height of 19 feet above the road's surface. The lowest areas were behind the Rodmans on the site of today's Batteries Cranston and Marcus Miller, where the shoulder was at grade, while the highest slope was behind the Rodmans on the site of present day Battery Godfrey. For most of its length, the outboard shoulder was usually only 1 or 2 feet in height.[34]

These elevations would start to change when work began on constructing the Endicott batteries that replaced West Battery, and land that had previously been at grade was suddenly raised by

[33] The author of this report directed once such project in the later 1980s at Battery Marcus Miller. The clearing work was carried out by members of the San Francisco Conservation Crew and extensive areas of earthen slopes and berms became discernible after clearing dense brush form the superior slopes. These outlines disappeared within a year, though, to returning vegetation.
[34] Drawing "Plan and Sections of Batteries for Fort Point" 1870.

several feet. The theory is that the vast quantities of earth and sand removed to make way for the new batteries were spread atop the natural terrain behind the batteries, resulting in a significant increase to the area's elevation.

For comparison purposes, I chose an arbitrary spot 50 feet east of Battery Marcus Miller gun #3, and tracked its elevation changes over the last 160 years. (Except for the last entry, all elevations are based on U.S. Army Engineer surveys.)

Year	Surveyed Elevation[35]
1847	Approximately 190 feet
1870	190 feet
1871	189 feet
1891	198 feet
1914	198 feet
1945	195-198 feet
2000	205 feet

The park's GIS expert has compared the relative accuracies of these historic surveys, and believes that they are correct to within 0.75 foot.[36] Given this variance, it is believed the terrain behind Battery Marcus Miller has been raised somewhere in the vicinity of 12 to 15 feet since 1847.

These filling activities appear to have occurred in two significant episodes: 1871–1891 and 1945–2005. The first episode, which resulted in an 8-foot elevation change, is probably associated with the construction of the Endicott batteries. Work began in 1891 on excavations for Batteries Marcus Miller and Godfrey, which coincides with this first increase.

These excavations were immense, and must have resulted in vast quantities of spoil. For example, the area occupied by Battery Marcus Miller measures 560 feet in length x 65 feet deep x 120 feet wide. An excavation this size would conservatively result in 161,177 cubic yards of spoil. It is theorized that this removed material was spread atop the natural hillside behind the batteries – the nearest flat dumping area adjacent to the battery site.

The possibility also exists that additional filling took place behind the batteries during construction of the Golden Gate Bridge toll plaza in 1936-1937. Photographs document that during this period, much of East Battery on the other size of the plaza was extensively filled (Figures 36 and 37). This activity resulted in the creation of today's Battery East Parking Lot

[35] Maps referenced are as follows: Lt. William Warner's 1847 survey of the Fort Point area, NARA, RG 77, W9; "Plan and Sections of Batteries for Fort Point" 1870. (GOGA, PARC, FOPO Collection; NARA RG 77, Drawer 94, Sheet 102); "Map Showing the Military Reservation of the Presidio of San Francisco," 1871 (PARC, GOGA, Drawer 211, Folder 1; NARA RG 77, Drawer 93, Sheet 4-23; "Gun Emplacements No 12-13 for 10 in. guns at Fort Point etc" 1891, GOGA, PARK, Drawer 27, Folder 2; NARA, RG 77, Drawer 94, Sheet 110-1; "Armament Sketches of Defensive Works in San Francisco Harbor" 1898, GOGA, PARC, FOPO Collection; NARA RG 77, Drawer 256, Sheet 10-16; "Presidio of San Francisco and Fort Winfield Scott, 1914 GOGA, PARC, Drawer 312, Folder 2; "Fort Winfield Scott" Harbor Defenses of SF Annexes, November 6, 1945, GOGA Archeology lab, Fort Scott drawer; Photogrametrical Presidio Contours (based on 1988 NAVD), 2000, GOGA, GIS mapping project.
[36] Interview with Hans Barnaal, GIS specialist for GGNRA, at Presidio Archaeology Lab, August 13, 2005.

adjacent to Lincoln Blvd.[37] However, any filling on the southern side of the bridge approach likely took place close to the toll plaza and outside the current project areas.

FIGURE 36 East Battery partly filled in October 1937. Compare to 1984 conditions in Figure 15. (Courtesy GGBHTD)

The source of the second episode behind Marcus Miller (an increase of 7 feet) is harder to pin down but probably occurred during the 1960s. The previously cited 1967 aerial photograph in the Golden Gate Bridge collection shows extensive filling operations occurring on the sites of both the Fort Scott dump and also behind Batteries Marcus Miller and Cranston. In this photo, the area between the batteries and Merchant Road is covered with freshly dumped piles of light-colored fill, each pile corresponding to about the capacity of a dump truck. Tire tracks can be seen among the piles, indicating dumping is still taking place.

The source of the fill is unknown, but could have been come from excavations for the "new" Letterman General Hospital on the Presidio, where construction was just getting started about this time. The area being filled is bounded roughly by the batteries on the west, Merchant Road on the south, and the Golden Gate Bridge employee parking lot. Today, this area is covered by extensive growths of nonnative vegetation and trees; additional (but informal) parking areas, many of them abandoned; and temporary modular office buildings associated with the Golden Gate Bridge's administration.

[37] Photograph in the GGBHTD collection, October 1937, Picture B1095.

FIGURE 37 Dumping activities occurring near Golden Gate Bridge toll plaza in May 1967. Battery Marcus Miller area at left, East Battery area at right. (Courtesy GGBHTD)

In short, today's deeply sunken "covered way" behind Battery Marcus Miller is not a vestige of the Plan of 1870s earthworks but rather the result of Endicott-era and later filling activities. The historic grade in this area should be considered the elevations that existed following completion of the Endicott works.

2.4 CULTURAL RESOURCES IN THE PROJECT AREA

The Presidio of San Francisco National Historic Landmark District is composed of significant historical, architectural, cultural landscape, and archeological resources associated with the long Spanish, Mexican, and United States military history of the property. It was originally designated in 1963 under the Historic Sites Act of 1935, and was placed on the National Register of Historic Places in 1966. Contributing properties within this National Historic Landmark are managed through the National Historic Preservation Act, and under 36CFR65 (National Historic Landmark Program), and special treatment responsibilities in 36CFR800:

> Sec. 800.10 Special requirements for protecting National Historic Landmarks.
>
> (a) Statutory requirement. Section 110(f) of the National Historic Preservation Act requires that the agency official, to the maximum extent possible, undertake such planning and actions as may be necessary to minimize harm to any National Historic Landmark that may be directly and adversely affected by an undertaking. When commenting on such undertakings, the Council shall use the process set forth in Secs. 800.6 through 800.7 and give special consideration to protecting National Historic Landmarks as specified in this section.

(b) Resolution of adverse effects. The agency official shall request the Council to participate in any consultation to resolve adverse effects on National Historic Landmarks conducted under Sec. 800.6.

(c) Involvement of the Secretary. The agency official shall notify the Secretary of any consultation involving a National Historic Landmark and invite the Secretary to participate in the consultation where there may be an adverse effect. The Council may request a report from the Secretary under Section 213 of the Act to assist in the consultation.

These contributing properties, and others with individual merit, are recognized in several national and state inventories used to facilitate the management of historic properties. Each has varying significance thresholds. Documentation prepared for these resources must also meet standards appropriate to these inventories.

(If it is not already evident), four structures are listed in current inventories of significant historic properties associated with the Presidio National Historic Landmark in the BBDA APE. These are:

- West Battery
- Battery Marcus Miller
- Battery Godfrey
- Battery Boutelle

Currently, these properties are represented in the following inventories (as shown in Table 2-1) used for cultural resources management by the NPS: the National Register of Historic Places Presidio National Historic Landmark Contributing Property Inventory (NHL), the NPS List of Classified Structures (LCS), the NPS Archaeological Sites Management Information System (ASMIS), the NPS Cultural Landscape Inventory (CLI), and the U.S. Army Presidio Building Inventory # (Army):

Table 2-1
Cultural Resources Inventory Designations

Structure/Site	NHL	LCS	ASMIS	CLI	Army
West Battery	F23	005949 005950 005952	GOGA-00025		1640 1643 1646
Battery Marcus Miller	F37	005955 005956			1658 1660 1661
Battery Godfrey	F39	005953			1647
Battery Boutelle	F45	005954			1651
Coastal Bluffs and Batteries: Presidio of San Francisco				725474	

GGNRA manages the West Battery Harbor Defense area in accordance with a Programmatic Agreement with the California Office of Historic Preservation and the Advisory Council on Historic Preservation. Under the provisions of this Agreement review of federal undertakings

involving historic properties (buildings, structures, archeological sites, ethnographic properties, and cultural landscapes) on the Presidio is conducted through the GGNRA Division of Cultural Resources as long as properties deemed eligible or already listed on the National Register of Historic Places are not adversely impacted or impaired by such undertakings. Projects that will impair such resources go must go through full consultation with Agreement signatories in accordance with the National Historic Preservation Act.

A *Seacoast Fortifications Preservation Manual* has also been produced to assist in the preservation and/or rehabilitation of elements of the fortification systems (Freeman et al. 1999). Repairs have been conducted on many parts of the deteriorating structures to preserve their condition for public interpretation. Most recently, all vegetation and trees were removed from Batteries Godfrey and Boutelle, and the earthworks were rehabilitated through revegetation with a specially designed native plant palette. All work was photographed and archaeologically monitored to ensure that structural and historic features were not impacted. Artifacts associated with the use of the batteries were recovered and accessioned into the GGNRA museum collection.

2.4.1 Field Reconnaissance of Baker Beach Remediation Project Area

Notes describing the survey of the Baker Beach Remediation Project Area are presented in Appendix A, Report of the Field Exercise Baker Beach Remediation Project, Archaeological Survey Field Notes. The goals of the field survey were to:

- Locate all remnant elements of West Battery, and previously unrecorded features.
- Agree upon the location/route of the "Covered Way" (the pathway that wound between the fortified earthworks and batteries of the coastal fortifications).
- Digitally map, with the Total Station, West, and Endicott Era structures that are within the current project's APE.
- Based on data derived from the field survey prepare a statement describing physical limitations on the usage of heavy equipment in the APE that could adversely affect historic features of the subject coastal fortifications.
- Conduct a shoreline pedestrian survey to identify discarded elements of the fortifications or shipwreck debris.

2.4.1.1 Results

The field crew was comprised of both URS archaeologists, Vance Benté, Sean Dexter, and Christopher Lee, as well as NPS and Presidio Trust archaeologists, including Leo Barker, NPS, Hans Barnaal, NPS, and Megan Wilkinson, Presidio Trust. Early focus of the survey was on the two West Battery magazines (#28-29) south of Battery Godfrey at the southern terminus of the project's APE. "Ground-truthing" elements of historic photos and maps were examined to see if battery features could be located. No evidence of prehistoric use of the area was encountered, nor were the earlier reported sparse scatters of shell observed. Two features of unknown origin and purpose were discovered during the survey. The first was discovered partially buried between Magazines # 28 and #29; it consists of a poured (in individual pie-shaped sections) and surfaced, circular concrete pad. It is approximately 12 feet in diameter, with a circular open center

approximately 24 inches in diameter. The surface has been painted with a thick coat of rust-colored orange paint similar to the color of the Golden Gate Bridge. Its function is unknown. Another partially visible circular concrete feature was discovered on the outer slope of West Magazine 29, and is likely an antiaircraft foundation. Remnants of the five West Battery magazines were located during the survey. The two southern West Batteries were mapped using the Total Station to capture accurate elevations. Completion of digital mapping was not completed during the two-day survey and it was concluded that NPS archaeologists, Leo Barker and Hans Barnaal, not URS archaeologists, would complete this task at a later date. Please see Appendix A, Report of the Field Exercise, for detailed notes of the Field Reconnaissance of the Baker Beach Remediation project area. Figure 38 Survey Results and Vegetation Removal, illustrates the location of the newly discovered features. Photographs of those features are included in Appendix A. Dense vegetation that effectively masked the site topography, and the absence of any specific plan that described the areas that would require remediation, or the manner in which the remediation would be undertaken, limited the usefulness of any evaluation regarding the usage of heavy equipment on the site. Structures with known subterranean hollow areas had been identified prior to the survey as areas that would require avoidance. No additional areas were identified as a result of the field survey.

2.4.1.2 Shoreline Pedestrian Survey

A significant amount of debris that appears to relate to structural demolition was observed along the shoreline at the base of the bluff, with a greater concentration below BBDA1 than BBDA2. In some cases, the structural elements were mixed with metal debris, e.g., axles, bolts, spikes, etc., and a possible ship's rudder. Although many of the concrete pieces were characterized by distinctly different aggregates, understanding of the construction practices throughout the Presidio over time is insufficient to make any reasonable statements regarding the source of this debris. None of the debris could be definitively associated with the bluff-top fortifications.

2.4.2 Field Sampling

Cultural resources studies were undertaken in concert with the geotechnical sampling at BBDAs 1, 1A, 2, and 2A. These studies obtained data essential to the design of a remedial action plan to avoid impact to significant features that compose the West Battery and Endicott Era coastal fortifications in the project are. Work included vegetation removal, designed to expose and allow surface mapping of the juxtaposition between historic earthworks and later landfills. Trenching assessed the relationship of the post-Endicott Era fill to the fortification features. Additional field and documentary data were collected to inform design of the finished condition to the remedial action plan. Archaeologists monitored activities during all phases of the brush removal and geotechnical sampling, and directed trench exposures and hand-excavations on the historic fortifications.

2.4.2.1 Vegetation Removal

Brush and tree removal was undertaken to improve visibility of the historic earthworks in preparation for the remediation sampling to follow. It also served to protect earthen historic resources by reducing the potential for damage caused by invasive root structures.

The removal process began on February 14, 2005, and continued intermittently through February 23, 2005. Periods of heavy rain required that clearing activities be postponed on February 15, 2005, owing to the potential for accidents and damage to historic resources.

In general, clearing was conducted in two areas: it began in the area bracketed by West Battery Magazines 27 and 28, on the southern end of Battery Godfrey. The fill area between Magazines 21 and 22 is known to be the location of West Battery mortar barbettes XLII through XLV. The area between Magazines 27 and 29 contains apparently incompletely constructed elements of West Battery magazines and gun pits LVIII to LXI. Notes and observations made by the in-field monitor that pertain to the day-to-day activities are included in Appendix B, Monitoring Notes. Figure 38 provides a graphic depiction of the area that underwent clearing.

To avoid damage to the landform, or near-surface archaeological deposits, the brush was consistently cut above the ground surface and no excavation to remove root systems was undertaken. Tree removal, specifically cypress tree in the Magazine 21 vicinity, was undertaken in the same manner to minimize alteration of the earthworks related to that feature and the adjacent covered way. Tools employed by the contractor included chainsaws, weed-whackers, and hand-pushed mowers. Waste was in some cases dragged from the site with a small backhoe, cut up, and mulched with a portable chipper. All waste was removed for off-site disposal.

Table 2-2 is a list of vegetative species removed from the area. Lewis Stringer, NPS biologist, provided this list to URS.

Table 2-2
List of Vegetative Species Removed from West Battery Area During Brush Clearing and Removal

Scientific Name	Common Name	Scientific Name	Common Name
Natives		**Exotics**	
Baccharis pilularis	Coyote Brush	*Anagalis arvensis*	Scarlet Pimpernal
Eriophyllum staechadifolium	"Lizard Tail" or Costal Wooly Sunflower	*Carpobrotus edulis*	Hottentot Fig
Fragaria chiloensis	Sand or Beach Strawberry	*Circium vulgare*	Bull Thistle
Mimulus aurantiacus	Bush Monkey Flower	*Conium maculatum*	Poison Hemlock
Scrophularie californica	California Figwort	*Delairea odorata*	Cape Ivy
		Raphanus sativus	Wild Radish

Artifacts Observed and Recovered

A variety of artifacts, primarily representing the day-use common to the area, were recovered in the course of the brush and tree removal. All collected artifacts were analyzed and delivered to NPS personnel at the Presidio Archaeology Lab. Table 2-3 describes those artifacts to be considered for formal inclusion in park museum collections. The remaining items were discarded and no further description or evaluation was undertaken. Discarded items included modern glass bottles, aluminum cans, plastic sunglasses, syringes, and objects related to the prurient activities practiced in the area prior to vegetation removal.

The artifacts recovered from the coastal slope adjacent to Battery Godfrey (Table 2-3) are representative of the materials that were recovered and provided to the NPS. This somewhat eclectic admixture of artifacts reflects refuse collection practices as well as disposal behavior following the period of fortification abandonment in this area of the Presidio, circa the late 1940s through the 1950s. Commercial refuse (e.g., a restaurant dairy bottle), demolition debris (e.g., industrial grade Siemens circuit breaker), soft drink containers, and drinking glass appear to have been collected and disposed of in a single episode. While all of the debris described here could represent activities occurring on the post, the possibility that the debris is the result of volunteer dumping by a nonpost entity cannot be dismissed.

While the brush removal provided better definition of the landforms and earthworks surrounding the historic properties, it did not reveal any previously unknown features or artifacts related to the West Battery or Endicott Era fortifications.

2.4.2.2 Geotechnical Test Pits

Goals and Procedures

The data obtained from the geotechnical investigation, undertaken by MACTEC and associated subcontractors, were to be used primarily to determine the extent of the post-Endicott Era fill, to describe the underlying soils and geology and to evaluate the suitability of the terrain to support heavy excavation equipment, and to provide soil samples for the characterization of the landfill wastes.

Because the test pits and borings would be excavated in areas immediately adjacent to known historic resources, or in areas where elements of those resources might have been disposed of, the NPS requested continuous on-site monitoring of the trenching. Test pit excavation was begun on April 5, 2005, and continued through April 19, 2005.

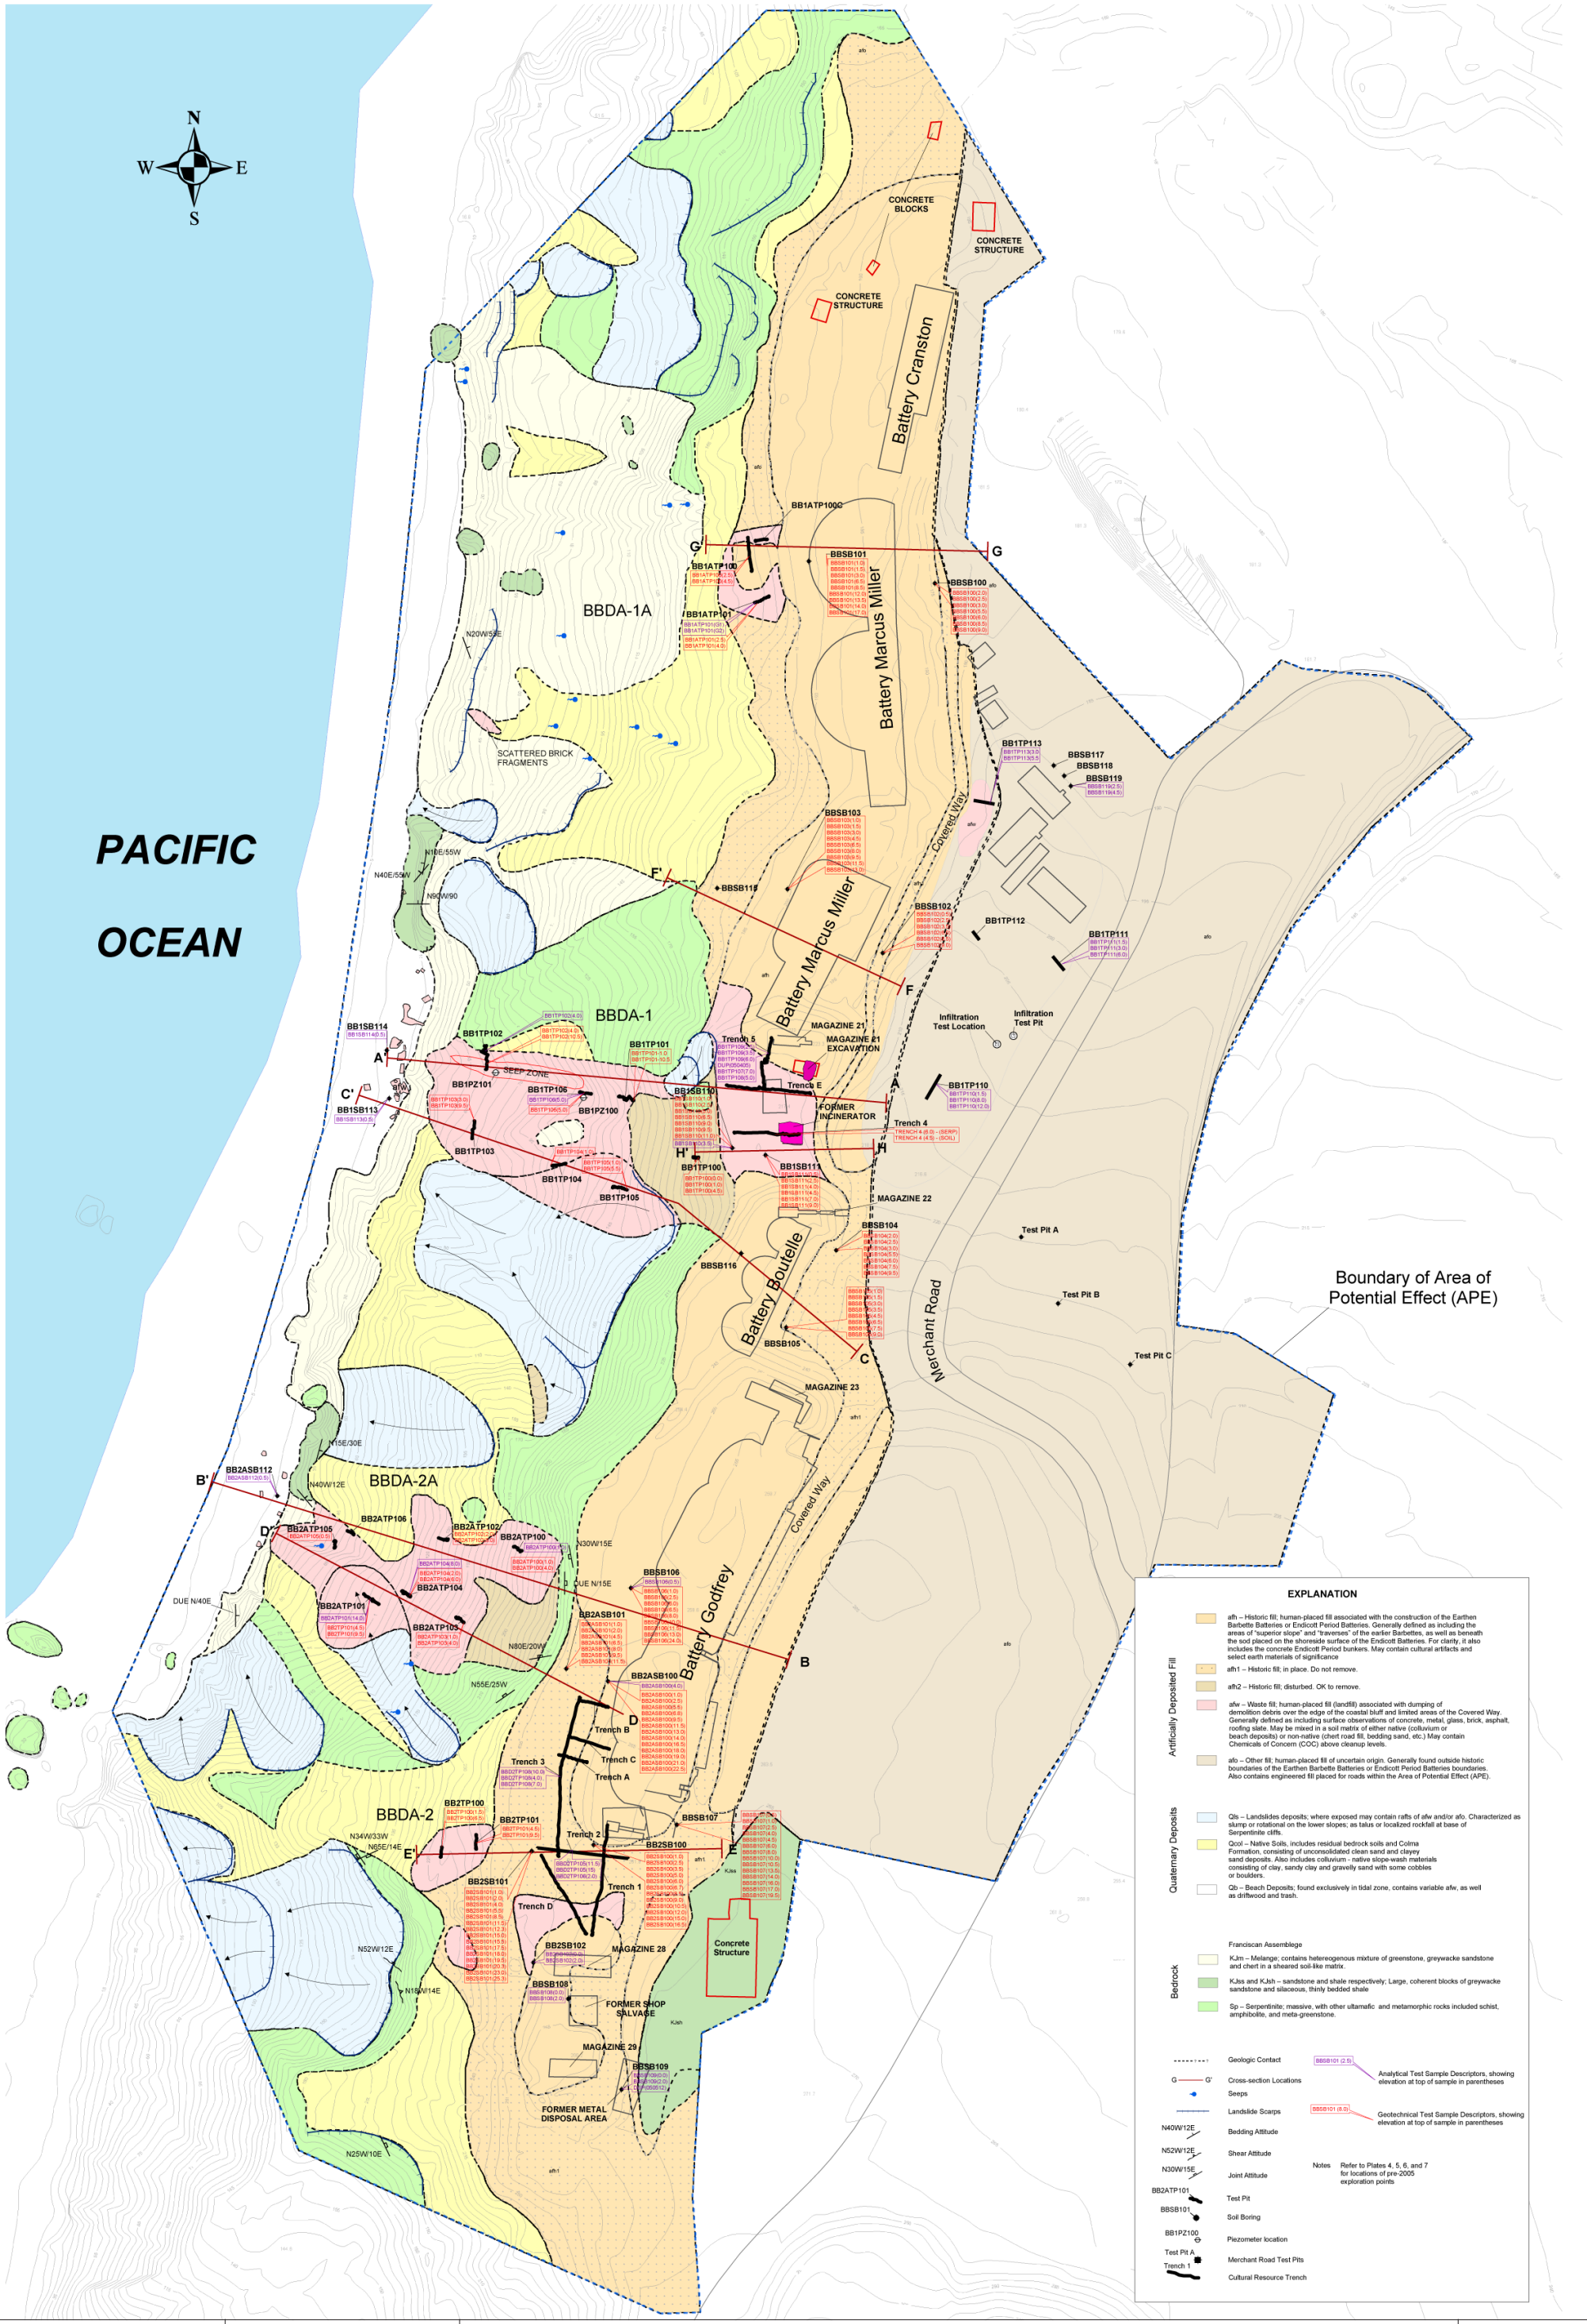
Trenching on the precipitous slopes was undertaken with a Kaiser S2 walking excavator equipped with a 24-inch-wide bucket. The test pits, essentially trenches, are depicted in Figure 39. A soils engineer and cultural resources specialist monitored each test pit. Specifics of the excavation can be found in the geotechnical sampling report.

A second phase of test pitting, undertaking as a result of information revealed by the historic research was conducted on October 3 and 4, 2005. These test pits, all in the vicinity of the covered way (Figure 39) were excavated to reveal the extent of post-Endicott Era fill along the covered way.

Results and Observations

This phase of the investigation was monitored on a continuous basis. A basic description of the stratigraphy, along with a characterization of the observed debris for each of the 21 test pits, is provided in Table 2-4. Test pit logs prepared by A. H. Henke are included as Appendix C.

None of the geotechnical test pits revealed substantial architectural or artifactual remains that provided new insights as the construction, use, or modification of either the West Battery or Endicott Era fortifications. The admixture of demolition waste and “domestic” debris appears to be mid-20th century refuse collected from throughout the post.



URS	26814549.SUPRE Baker Beach Cultural Landscape	Geologic Exploration Map (MACTEC)	Plate 39

Trench 1 in the Baker Beach Test Pit 102 vicinity encountered a substantial accumulation of debris suggesting a long-term residential occupation. Those items are described in Table 2-5. The presence of ceramic items with backstamps that include reference to the Quartermaster indicate the source of the refuse to be from a post-related occupation; however, the specific population is unknown.

A few of the artifacts recovered from Test Pit 102 have manufacturer's marks that are sufficiently diagnostic to suggest that the debris accumulated over a period ranging from the late 1940s through the mid to late 1950s (e.g., the "D-patent" Coca Cola bottles, produced from 1938 to 1951; and the mark of a ceramic manufacturer, Technical Porcelain and Chinaware Company [TEPCO] 1922-1972, located in El Cerrito, CA. The "TEPCO/U.S.A./CHINA" mark was first used in 1954, and subsequently registered in 1955).

As described in the historic context, two incinerators were built on the bluff in the BBDA-1 area, adjacent to the west of the parapet and mortar platforms known to have been situated between Traverses 21 and 22. The first of the incinerators was built in 1917; it was subsequently replaced in 1934. Citing a relationship between the sheet-refuse encountered by the test pitting on the face of the bluff and the disposal activity evinced by the incinerators is attractive; however, they may not be related.

The majority of artifactual materials encountered appear to date from the late 1930s/early 1940s through the 1950s, significantly postdating the first incinerator but possibly related to the second. Further, no significant deposits of ash were encountered, nor did a substantial number of the artifacts observed or recorded appear to have been subjected to high heat. One possible explanation for this apparent disconnect is that waste was separated and the noncombustibles were dumped over the bluff.

Table 2-3
Artifacts Recovered During Vegetation Removal

Additional Comments	Artifact Description
Large clear glass jar, barrel-shaped, with embossed lines to mimic barrel staves and hoops.	Base embossed with: "425-65," "13," "4," and "Ball" (in cursive).
Clear drinking glass.	Bottom embossed with: "C," two intersecting diamonds, and "4" (along top), "6" (at bottom), and "6181" above it.
Coca Cola bottle, Georgia green, complete.	Manufacturers mark of the Maywood Glass Company, CA, used circa 1940s.
Dr. Pepper bottles (2), clear glass. Both complete. Both are debossed with a stylized clock pointing to 10, 2, and 4.	Owens-Illinois Glass Company marks with plant designations for Oakland and Los Angeles, suggesting manufacturing dates as late as 1954.
Half-pint dairy bottle. Front is stenciled with: "GREEN GLEN DAIRY SAN FRANCISCO," in green; back in green letters: "WHY COOK AT HOME? RESTAURANTS OFFER A VARIETY; FOR EVERY TASTE."	Established in 1937, the Green Glenn dairy provided products to the three main restaurant chains in San Francisco. The history page on the company website notes, "During the war the business flourished as a major supplier to the service personnel in San Francisco."
Glass fragment (smoked) (1 cm thick).	
Ferrous metal pipe end - open only on one side; badly corroded.	
Molded case circuit breaker manufactured by ITE Siemens – has opening in center with "on" at one end and "off" at the other, two rusty screws remain attached. A switch that fits in the center aperture was found in association, but is separate.	
Metal and plastic electrical assemblies, all screws missing and metal parts rusty; may be electrical equipment related to the above breaker.	
Two cast-metal light fixtures with porcelain sockets; plastic-coated copper wires (black and white) protrude from each piece.	

Table 2-4
Baker Beach Test Pits – Basic Stratigraphy and Characterization of Debris (Reference Figure 39 for location of Test Pits)

Area/Test Pit	Stratigraphy	Characterization of Debris
Baker Beach 1		
BB1TP100	Dark, blackish-brown, sandy-silt, over a 7-foot layer of soils mixed with debris, above concrete rubble. Rubble halted further excavation at 8 feet.	Debris observed in 7-foot fill layer included corroded metal, nails, screws, spark plug, and concrete.
BB1TP101	Fill in this area continued to a depth of 17 feet, the maximum reach of the excavator.	Debris consisted of a melted piece of aqua glass, one fragment of white-improved earthenware, a fragment of orange-colored marble, a medicinal bottle and a condiment bottle both machine-made, and a single piece of white porcelain marked with an eagle and the words "United States Army."
BB1TP102	Fill to approximately 11 feet – bedrock was not encountered.	A representative collection of the domestic debris mixed with construction debris was collected for review in the NPS laboratory. Materials included broken and whole bottles, white-improved earthenware, porcelain, concrete rubble, and metal debris. In-field dating placed the deposit in the 1930s to 1940s; review of the materials suggests deposit was made in the late 1940s or 1950s.
BBTP103	A 10-foot layer of fill overlying serpentinite bedrock.	Debris included screw-top medicine, wine and liquor bottles, porcelain and white-improved earthenware sherds, corroded metal, asphalt and slate roofing, and roof tiles. In-field dating places the deposit in the 1930s to 1940s; review of the materials suggests the late 1940s into the 1950s.
BB1TP104	A 9-foot layer of fill overlying a Franciscan outcrop. Interbedding of debris with shale suggest periodic disposal.	Debris consisted of concrete rubble, tar, roofing material, and corroded metal.
BB1TP105	A fill layer, mixed with debris, extended to a depth of 11 feet, bedrock encountered at 14 to 18 feet.	Debris consists of concrete rubble, brick, layers of mortar, corroded metal, slate roofing, and a few glass bottles with screw-top closures, which appear to date to the 1930s-1940s.
BB1TP110	A 3-foot layer of fill with concrete and brick, over a 1 ½ foot thick layer of cobbles, over fill transitioning to sterile native colma – fill is perhaps 6 to 7 feet in depth	Brick and concrete mixed with earth fill
BB1TP111	Chert bedding layer encountered at approximately 2 feet below surface, over 4-5 feet of colma, transitioning to native colma at 7 feet.	Brick and concrete mixed with earth fill

Table 2-4 (continued)
Baker Beach Test Pits – Basic Stratigraphy and Characterization of Debris (Reference Figure 39 for location of Test Pits)

Area/Test Pit	Stratigraphy	Characterization of Debris
BB1TP113	Chert bedding layer, over an asphalt layer encountered at 2 feet, over a fill layer 3 to 4 feet in depth, native colma encountered at 7 feet	Fill contained rebar, concrete, brick debris, rubber bumper, pull-tabs from cans, "Mickey's Malt Liquor" bottle
Baker Beach 1A		
BB1ATP100	3 feet of dark, blackish-brown sandy silt, trending to serpentinite rock at 3 to 4 feet.	A single brick was recovered from the upper level, no other debris or artifacts were encountered. An extension of this test pit to the north revealed no additional debris.
BB1ATP101	4- to 6-inch layer of debris, overlying a dark, blackish-brown layer of sandy silt, with decomposing serpentinite at base (approximately 5 feet in depth).	Debris layer consisted of roofing materials.
BB1ATP102	1 foot of top soil over approximately 3 to 3.5 feet of debris, overlying Colma formation soil above a serpentinite rock formation.	Debris consisted of the macadam-like material (tar and sand) used on the roof surfaces of the batteries.
Baker Beach 2		
BB2TP100	18-inch top soil layer over sterile native soil (Colma Formation). No excavation beyond approximately 6.5 feet.	No debris of historic materials encountered.
BB2TP101	3- to 6-inch layer of top soil over a 12- to 18-inch layer of debris, over a 6.5-foot layer of sandy, silt soil with serpentinite inclusions. A serpentinite rock formation was encountered at 9.5 feet.	Debris was composed of concrete, brick, tile, rusted metal, wire, and glass fragments. An intact television cathode ray tube (screen tube) was recovered; a "D-Patent" Coca-cola bottle (production dates 1938-1951).
Baker Beach 2A		
BB2ATP100	Original location could not be accessed (April 14, 2005). Original TP101 location became TP100. Fill layer to approximately 3 feet, overlying serpentinite bedrock.	Debris consisted primarily of wood, broken glass, and slate roof tiles. Concrete rubble was not observed in large amounts.
BB2ATP101	Moved to a location south of BB2ATP104.	Debris consisted of large metal construction pieces, e.g., "I" beams, axel and spring assemblies from an automobile; other elements of the fill included slate roofing, wood, broken glass, white-improved earthenware, porcelain sherds. A distinct layer of brick was encountered at an approximately 7-foot depth.

Table 2-4 Concluded
Baker Beach Test Pits – Basic Stratigraphy and Characterization of Debris (Reference Figure 39 for location of Test Pits)

Area/Test Pit	Stratigraphy	Characterization of Debris
BB2ATP102	Fill extended to a depth of 7 feet, overlying serpentinite bedrock at 8 feet.	Debris consisted of a concrete post or pillar, melted glass, white-improved earthenware, porcelain sherds, bottles, a fragment of marble, and wooden posts and siding. No slate, brick, or tar roofing material was observed.
BB2ATP103	Fill to approximately 5 feet.	Minimal debris – a large piece of metal wire.
BB2ATP104	Fill to a depth of 12-14 feet. Excavated to 21 feet.	Debris consisted of concrete rubble, tile, slate, roofing materials, along with a Dr. Pepper bottle, a Shield's Harper and Company Motor Oil container, a green glass wine bottle, a vinegar bottle, and a brown glass medicinal bottle.
BB2ATP105	Serpentinite bedrock encountered at 6-inch depth.	No debris recorded.
BB2ATP106	Serpentinite bedrock encountered 6-inch to 2.5-foot depths.	No debris recorded.

Table 2-5
Baker Beach Disturbed Area 1- Test Pit 102 Representative Artifact Description

Description	Count
Ceramic	
Missionware plate fragment, pink with fuchsia roses, green leaves, and blue flowers.	1
White improved earthenware base, with blue band on rim and windmill design in blue, black, orange.	1
Blue/purple porcelain, possible plate fragment.	1
White porcelain plate base fragment, white glaze with thick black stripe around rim of plate and a thinner red/orange stripe below it around rim.	1
Porcelain base fragment, light blue glaze, possible plate.	1
Aqua blue porcelain bakeware or mixing bowl fragment; crazing on finish.	1
White porcelain bowl fragment; with a thick dark green band around rim and a thinner green band below it around rim.	1
White porcelain base fragment; possible mug or bowl.	1
Porcelain light fixtures, with screws/metal attachments, one piece has [BRYANT] embossed on underside; may be parallel wire knob and tube type.	4
Porcelain mug, plain white, complete, on bottom of mug in black ink: [TEPCO U.S.A. CHINA] (Technical Porcelain and Chinaware Company, 1922-1972, El Cerrito, CA) specific make first used in 1954, registered in 1955. (Lehner 1988: 468-469).	1
Thick white porcelain mug, nearly complete (part of the body is missing so it may or may not have had a handle); on bottom of mug in blue ink, written in a circle: [ROYAL CHINA INC./ SEBRING OHIO] (1934 to present, Lehner 1988:83).	1
Thick white porcelain mug, approximately half of the mug (part of the body is missing so it may or may not have had a handle); base is mostly gone but a hint of blue ink (and its size) suggests it is a mug identical to the example above.	1
Thick white porcelain mug, approximately half of the mug (part of the body is missing so it may or may not have had a handle; base is mostly gone but the letters [CO] in blue ink suggests it is a mug identical to the "TEPCO" example above, or is it "SAN FRANCISCO CALIF CO"? Half of the specimen, on both the exterior and interior, has a grayish pattern on the glaze, suggests being in the presence of heat?	1
White porcelain rim and body fragment of same type of mug as noted in above examples; base missing.	1
White porcelain mug body fragment of same type as noted in above example.	1
White porcelain gravy boat fragment, nearly half of a complete specimen, with half of base, rim, and body present; handle broken off; on bottom of base in blue ink, [U.S.Q.M. NEW CASTLE, MA]; same thickness as mugs noted above.	1
White porcelain container, possible sugar bowl or condiment container, half of base and a fragment of the body; on base in blue ink [U.S.Q.M./W 4 (6?) 31 QM 4-28-41]; same thickness as above-mentioned gravy boat and mug fragments.	1
White porcelain three-section plate, same thickness as all above-mentioned articles; plate is divided into at least 3 separate sections; on base in red ink: [TEPCO/ VITRIFIED/ MADE IN].	1
White porcelain bowl fragment (slightly less than half); including some base and rim; no inscriptions/maker's marks.	1

Table 2-5 (continued)
Baker Beach Disturbed Area 1- Test Pit 102 Representative Artifact Description

Description	Count
White porcelain bowl fragment, smaller sized than above example but same thickness; including some base and rim but no identifying marks.	1
White porcelain vase or pitcher fragment, including portion of rim but no base; slightly less thick than above example (approximately 4 mm thick as opposed to 5 mm); one nonrounded corner suggests spout; no identifying marks).	1
White porcelain bowl fragment of same thickness as above pitcher fragment; some rim and base present but no identifying marks.	1
White porcelain plate fragment of same thickness as above pitcher and bowl fragment; some rim and base present, plate NOT divided into portions (as the other plate fragment was); no identifying marks.	1
White porcelain plate or shallow bowl fragment, some rim and base present, but no identifying marks; thinnest example of this group (approx. 3 mm).	1
Glass	
Glass or slag, black.	1
Green wine bottle, complete, with small push-up base and double ring neck finish. [BOTTLE MADE IN ITALY] embossed around edge of base.	1
Milk glass jar bottom; embossed in circle in center of base: [CORNING] (around top); [T.M. REG.] (in center, with a small human figure between them); and [MADE IN U.S.A.] along bottom.	1
Green glass bottle, complete. Embossed [COCA COLA/TRADEMARK REGISTERED/MIN. CONTENTS 6 FL. OZ./D-1055 29/SAN FRANCISO CALIF.]; D-patent Coca-Cola bottle produced 1938-1951.	1
Clear glass ketchup bottle, complete, no label or writing on sides; bottom of body is divided into 8 "sides," embossed on base: [12], a diamond superimposed over an oval (Owens-Illinois glass company, Toledo, OH); [0] (all on the same line); and [8] below the diamond symbol (1929-1954, plant # adds no additional definition.)	1
Clear glass ketchup bottle, nearly complete (part of neck is broken off); similar in shape to above bottle but not as tall; embossed on base: [H-257] (in center) and below that, the letter [H] over the letter [A] (symbol of the Hazel-Atlas glass company, Wheeling, WV), and the letter B, 1902-1964.	1
Clear glass condiment bottle, complete, no label or writing on sides; bottom of body is divided into 10 "sides" on bottom base, likely D-patent Coca-Cola bottle produced 1938-1951.	1
Amber bottle fragment, top and neck portion with just the slightest part of the body remaining; plastic orange cap is present and twists on and off.	1
Clear glass jar bottom, embossed on bottom: [GLAS] in cursive on top; [STORE] in large letters in center, and [23], a diamond is superimposed over an oval (Owens Illinois, Toledo, OH), and [3] along the bottom; on side: [ONE QUART/1719]. The #23 could represent the Los Angeles, CA plant, which did not open until the late 1940s.	1
Clear glass jar bottom, complete base, embossed on bottom: [4-9] on top, the letter [H] over the letter [A] (symbol of the Hazel-Atlas glass company, Wheeling, WV) in the center; and along the bottom: [K 625] (1902-1964).	1
Clear glass condiment bottle, [1916-0] embossed on bottom.	1

Table 2-5 (concluded)
Baker Beach Disturbed Area 1- Test Pit 102 Representative Artifact Description

Description	Count
Small blue glass Noxzema cosmetics jar, lid missing but otherwise complete, the number 2 and the word [NOXEMA] embossed on base, with the [Z] being very large and dividing the word in half ([NOX] on one side, [EMA] on the other).	1
Small blue glass Vicks cosmetic/medicine jar, lid missing but otherwise complete; embossed on bottom: [VICKS] (around top of base); a triangle (in center); and [VA-TRO-NOL] along bottom.	1
Blue glass vial or small bottle; [7] on bottom, [BROMO SELTZER EMERSON DRUG CO.] embossed on side.	1
Milk glass bottle, lid missing but otherwise complete; on bottom of base: [METHOLATUM 5 REG. TRADE MARK]	1
Small clear glass bottle, lid missing but otherwise complete, no markings except on bottom of base,: [DR LYONS TOOTH POWDER] around circ. of base, with the number [5], the [A] in a circle, and [43] along the center.	1
Clear glass bottle neck, threaded? Lines are spread wide apart.	1
Dark blue bottle glass, fragment of the base and some of the body; the letters [OPS] are visible on the base.	1
Clear glass bottle neck/top fragment; melted/burned and as a result is twisted and distorted.	1
Clear glass base fragment.	1
Indeterminate clear glass fragment; melted/burned", circular pattern on one side (possibly structural).	1
Green glass soda bottle body fragment; red and yellow paint residue present; the word [ROYAL] is etched into the body and was probably painted; possibly Royal soda	1
Indeterminate clear glass fragment; thick (approx. 5 mm) with a raised bubble pattern on upper surface; possible crazing? Structural?	1
Indeterminate clear glass fragment; about the same thickness as above specimen, but no rim or base visible; entire surface is cracked/crazed with bubble-like pattern; possibly structural.	1

2.4.2.3 Battery Godfrey / West Area Archaeological Investigation (BBDA 2, 2A Area)

The BBDA 2 landfill is located on the bluff-top at the southern end of the parking lot situated on the western side of Battery Godfrey as show on Figure 39. Given the location of Battery West, as derived from historic documentation and field observations, it appeared as though portions of the landfill were likely to be superpositioned on the earthworks of West Battery Magazines 27 and 28, and the frontal slope of Battery Godfrey; however, the nature, depth, and horizontal extent of the fill was unknown.

Goals

To obtain sufficient data on which to design the remedial action plan in a manner that would avoid or minimize damage during remediation to either of the Battery West magazines or the frontal slope of Battery Godfrey, two trenches at approximate right angles were to be excavated in the parking lot area between West Battery Magazines 27 and 28. These trenches were intended to capture data that would provide definition of the stratigraphic relationship between modern landfills and historic earthworks, to include identification of original grade period grades, the earthen fill related to each phase of construction, and the relationship of landfills to earth and concrete structures of West and Godfrey batteries.

These data were viewed as crucial to complete the necessary identification and effect assessment of the resources known to be within the area of BBDAs 2 and 2A; provide essential metrics as to the extent of the deposit requiring remediation; and provide data essential to the post-remediation restoration of the location, once the modern landfills are removed.

Figure 39 depicts each of the trenches that were eventually excavated. As anticipated in the *Cultural Resources Investigation Sampling Plan* (The Presidio Trust 2005), the lengths, orientations, depths, and number of trenches required modification as the subsurface layering was revealed. Additional exposures were excavated to capture data that were required to expose and interpret the stratigraphy encountered in the two planned trenches, and then further define the debris fill encountered within those trenches.

Trenches were excavated with a conventional backhoe equipped with a 24-inch bucket with three teeth, or a 24-inch bucket with a toothless cutting blade (“butter bar”), the latter employed in circumstances requiring a cleaner cut. Fieldwork for the first portion of this work began on April 25, 2005, and continued through April 29, 2005. All trench excavation was continuously monitored by a minimum of two archaeologists.

Discussion of Results

Figure 39 illustrates each of the trenches relative to the project area. Detailed soil profile drawings are provided in Appendix D (prepared by Anna H. Henke, MACTEC), for each of the trenches (BBDA1 and BBDA2), 1 through 5, and A through E (Subappendices D-A1 through D-A10). Subappendices D-A11 and D-A12 provide a schematic of the relationship among the Battery West magazines, the frontal slope of Battery Godfrey, and the mortar platforms between Magazines 21 and 22. Figure 40 depicts the trenches as they relate to the 1890 West Battery armament sketch. Casual review of the profiles would suggest that each of the trenches was excavated at a separate and distinct site, in fact, while the stratigraphy has some unifying

regularities, the subsurface is remarkably variable depending on where it is exposed and observed. Overlays, depicting the cultural stratigraphy were prepared as an aide to the discussions that follow. The overlays are bound separately and located in the rear pocket of this report as (Attachment 1: Overlays 1-8). Trenches were not excavated in a strict numeric or alpha character sequence. However, they will be presented in this report in alpha/numeric sequence for ease and clarity of review.

Trench 1. Trench 1 traverses the current roadway between Magazines 27 and 28. It was excavated primarily to reveal the relationship of the fill beneath the access road to the parking area located on what was Battery Godfrey's historic frontal slope, and to the original earthworks related to each of the adjacent Battery West magazines.

As is evident from the soil profile (Appendix D-A1), the area immediately south and adjacent to Battery 27 has been the site of numerous cut-and-fill episodes that are capped with a layer of chert, which serves as the present day road surface. The presence of large quantities of waste/excess concrete (slurry "cleanout" deposits) at the edge of the roadway and extending south to the continuation of the landform that is a portion of Magazine 28 suggests that the area was once a recognized disposal point. However, the stratigraphy revealed by this trench does not indicate that the waste fill located here encroaches on intact landforms related to the magazines. There appears to be no buried remnant of any earthen parapet, which Magazine 27s and 28 would have been traverses from, as evidenced between Magazines 28 and 29 to the south.

The stratigraphy revealed by Trench 1 (see Attachment 1: Overlay 1) adjacent to each of the magazines demonstrates the 1870 era construction practice of defensive soil placement (illustrated in black and described as "black lean clay 10YR2/1") alongside and above the mortar and brick structures of the magazines to absorb the impact of incoming fire. However, reference to descriptions, plans and drawings, and photographs of magazines that were part of West Battery and other that were coeval with it, suggest that these soils are only remnants of the earthworks over the magazines, and that in some cases raised the elevation as much as 9 feet (see discussion of Magazine 21 that follows). The 1870s earthworks were added primarily as means to protect the magazine structures from aerial bombardment and their resulting visibility was not considered an issue at that time, as is evidenced by the bluff-line profiles illustrated on Figures 20 and 21.

Subsequent changes in the philosophy of warfare and related construction of fortified emplacements during the Endicott Era required reshaping of the bluff-line profile to reduce visibility of the earthworks. As noted under *Alteration to 1870s Traverses* in Section 2.3.2.4, the 1870s era batteries were so pronounced that its earthworks and guns were even visible from Pacific Heights. Colonel Eben E. Winslow noted in his 1920 treatise, *Notes on Seacoast Fortification Construction*, that during the Endicott Era when the disappearing [gun] principle was introduced into seacoast gun carriages, it became desirable to conceal the gun and, therefore, it was desirable to reduce the height of the traverse to the parapet. Additionally, Emmanuel R. Lewis (1965) notes in *A History of San Francisco Harbor Defense Installations: Forts Baker, Barry, Cronkhite, and Funston* that, "With the development of the modern disappearing carriage, however, most of the batteries were to have an uninterrupted, horizontal crest line, which would render them extremely difficult to pinpoint from the seaward direction. This requirement–to hold the tops of the traverse to the level of the parapet–created an interesting design problem, for it demanded a substantial lowering of the magazines if adequate cover was to be maintained."

The minimal depth of soil on the top of the structures and the addition of soil on the flanks of each magazine may be evidence of this evolution of design, form, and function. The black soil unit on the side of each magazine is covered and interbedded (Figure 41) with a substantial soil unit described as mixed clay fill (10YR5/6). The source of these strata is likely the excavations required to produce landforms appropriate to Endicott Era construction goals with obsolete West Battery magazine landforms. Based on observable interbedding of the two soil units it appears that the earthworks were removed from the tops of the magazines during the Endicott construction period, and that those soils, augmented with soils taken from Endicott excavations, were used to "dampen" or modulate the topography. In the area adjacent to Magazine 27 it appears that the Endicott Era deposition extended southward to the limits of the cut surface, and was graded to accommodate the roadbed represented by the chert fill.

FIGURE 41 Interbedding of Soil Units

In the area immediately adjacent to Magazine 28 (See Attachment 1: Overlay 1) it appears that the cut surface at the base of the magazine represents the original excavation made to accommodate the magazine construction, which was subsequently capped with the same mixed-clay fill observed in the profiles at Magazine 27. The slope of the cut is observable also in Trench D, which was excavated to determine the relationship of the concrete and debris fill, encountered in Trenches 2 and 3, to the northeastern extent of Magazine 28. As demonstrated by Subappendix D-A1, the debris and concrete do not appear to encroach on the intact stratigraphy contemporary to the Endicott Era.

A few additional details revealed by Trench 1 are notable. The near vertical cut surface shown at the base of Magazine 27 is likely the original builder's construction trench. The brick pavement encountered at the bottom appears to have been a construction "landing" or walkway of some sort. The cut surface extending upward is thought to represent cutting during the Endicott construction period that was subsequently filled to achieve the more modulated surface required by the times.

Trench 2. Trench 2, which is essentially perpendicular to Trench 1, was excavated primarily to define the limits of the subsurface debris encountered at the southern end of Trench 3. Grading for the chert surfacing, of the parking lot, is clearly evidenced in the profile of Trench 2, as is the use of the western end adjacent to the bluff as a disposal area that was subsequently capped by the chert surface of the parking area (see Subappendix D-A2). The intriguing stratum with respect to both the Battery West and Endicott Era construction sequences is the clay (1) layer that presents an even gradient from the cut surface approximately midway in the trench to the western end of the trench. Although this clay layer was classified as natural, the nature of the soil

and contrast with adjacent soil types, its repose and abrupt interface with the clay (2) layer suggests that it may be the "sodded" frontal slope (exterior slope or glacis) relating to Battery West. If so, the sandy silt layer may represent Endicott Era alteration. Alternatively, clay (1) layer may represent the finished Endicott Era frontal slope, subsequently buried by post-Endicott fill episode sand and eventually the parking lot surface (See Attachment 1: Overlay 2).

The artifactual materials recovered from the debris fill toward the western end of Trench 2 are presented in Appendix E. While the vast majority of the artifacts appear to represent mid-20th century disposal, a single bottle base, embossed with the markings of the "California Bottling Co./John Weiland's Export Beer," was recovered. Wilson (1968:173) places the bottling of Wieland's Export Beer between 1894 and 1900.

The chronological gap between this single specimen and the remainder of the assemblage is noteworthy. A number of possible explanations compete to explain its presence: (1) that this single bottle is evidence of a lower component of the dump that dates to the 19th century; (2) one of the dump loads in the mid-20th century contained significantly dated debris; or (3) that someone, much like the behavior of modern San Franciscans, visited the bluff and enjoyed a bottle of beer, and discarded the bottle over the bluff. The latter scenario may be a bit tenuous as the area was a military reservation at the turn-of-the-century; however, the visitor could have been a member of the military.

Trench 3. Trench 3, bisected the parking lot north to south and exposed the debris deposition adjacent to the bluff. This trench also reveals the relatively uniform depth and character of the clay (1) layer that is believed to represent the prepared surface of the frontal slope that may be related to Battery West and/or Battery Godfrey.

Trenches A, B, and C. Trenches A, B, and C were each excavated to evaluate the relationship of the Battery Godfrey frontal slope to the existing parking lot, and to the fill revealed by Trench 3. The relationship of the mixed clay fill soil unit to the clay (1) soil unit in Trench A is suggestive of the relationship of these same two soils units as exposed by Trench 1 adjacent to the magazines. The relationship is perhaps predictable as it is consistent with the supposition that the clay (1) soil unit is the prepared surface of West Battery, and the mixed clay fill unit above it represents additional fills placed to form the earthen frontal slopes of Battery Godfrey (See Subappendix D-A4 and Attachment 1: Overlay 4).

Verification of this interpretation was not forthcoming from Trench B, as it could not be demonstrated that the mixed clay fill and clay (1) soil units articulated with the actual structure of Battery Godfrey or what might represent a related construction trench. Beneath the chert surface, from the edge of the battery, west for some 20 feet the trench exposed a layer of fine fill sand. The trench was abandoned at a depth of approximately 3 feet as the sidewalls were unstable and collapsing. Mixed clay fill was exposed at 20 feet west to the junction with Trench 3. The sand appears to be a late 20th century intrusion as sheet plastic was observed in the sand.

Trench C provides "weak" confirmation of the relationship of the mixed clay fill soil unit to the Clay (1) unit and the historic relationship to Battery Godfrey. The trench, as depicted in the soil profile drawing, shows the clay (1) layer approach the battery structure with an abrupt interface

between it and the mixed clay fill layer, thought to represent post-construction backfill and purposeful modification of the slope to obscure the location of the battery.

Trench D. Trench D was excavated from the north-facing slope of Magazine 29 to the northwest to expose the current condition of the Magazine 29 earthworks and to further evaluate the proximity of the landfill exposed by Trench 2 to Magazine 29. As depicted in the Trench D soil profile, the earthworks associated with the West Battery construction sequence and the Endicott Era construction sequence appear to have been removed, leaving a thin mantle of the original cover atop Magazine 29 and a remnant of the Endicott Era fill that are not covered by top soil.

Some 30 feet northwest of the vent towards the western end of the magazine is an area 20 to 22 feet in length that consists of solidified concrete. This deposit appears to represent the disposal of excess wet concrete and related washout of concrete delivery trucks.

Beyond the concrete, a layer of Endicott Era fill is found above remnants of the West Battery earthworks. The Endicott Era fill is capped with Post-Endicott Era fill and a chert base, similar to Chert Base or Road Bed B. The landfill encountered by Trench 2 is approximately 60 feet northwest of the magazine and capped by the same chert layer.

Summary

The clay (1) stratum revealed in 5 of the 6 trenches (1, 2, 3, A, and C) appears to represent an introduced soil layer that was used to prepare a base for the sodding, or may constitute the "sodding" of the Battery West fortifications. Subsequent demolition and modification of the Battery West structures to accommodate the construction of the Endicott Era fortification required the cutting and redistribution of that soil unit. Upon completion of the construction and in conformance with design requirements of the period, fill–the mixed clay fill stratum–was then introduced to "camouflage" the landform.

While Trenches 2 and 3 encountered substantial amounts of debris fill and the area was used historically to dispose of excess wet concrete, none appear to encroach on the intact portions of the magazines or battery. The one exception is the chert road surfacing on the southern side of Magazine 27, which rests on the Endicott Era mixed clay fill. Thus, removal of the fill in this area would serve in part to restore the landform related to the Endicott Era, a topic that is addressed in greater detail in the discussion that follows.

2.4.2.4 Battery Boutelle/Marcus Miller/West Area Archaeological Sampling (BBDA 1)

The BBDA 1 landfill, the majority of which is located on the western, sea-facing slope, was also in evidence on the bluff-top swale between Magazine 22 on the northern side of Battery Boutelle and Magazine 21 on the southern side of Battery Marcus Miller (Figure 39). The swale between the two batteries was the historically recorded location of the West Battery Mortar Barbettes XLII-XLV. Armament sketch maps prepared in 1898 depicted four squares, each believed to represent a wooden mortar platform and three parallel lines with elevations seaward of the squares, representing an associated earthen parapet.

Observable portions of the fill along the bluff appeared to be an admixture of large pieces of concrete and soil. While the nature, depth, and horizontal extent of fill was unknown, the fill adjacent to the entry of Magazine 21 was of sufficient depth to leave only the upper one foot of the magazine entrance visible.

Goals

To obtain sufficient data on which to design the remedial action plan, in a manner that would avoid or minimize damage to either of the Battery West Magazines 21 or 22 or elements of the mortar barbettes that might be buried beneath the fill, two trenches were to be excavated in the swale between Batteries Marcus Miller and Boutelle, and a single areal excavation was to be undertaken to remove fill from the partially buried doorway of Magazine 21 (Figure 39). The trenches and areal excavation were intended to capture data that would provide:

- Definition of the stratigraphy to include identification of the original grade, the earthen fill related to each phase of construction, and the relationship of the fill to the structure
- Identification and definition of relationship of the landfill debris to each structure
- Expose the entrance of and provide entry to Magazine 21, so that a condition assessment, including a structural evaluation, could be undertaken
- Data defining the presence/absence of the superior slope, parapet wall, mortar platform, and covered way

These data were viewed as crucial to complete the necessary identification and effect assessment of the resources known to be within the BBDA 1 area, provide essential metrics as to the extent of the post deposit requiring remediation, and provide data essential to the postremediation restoration of the area/resource.

Figure 39 depicts each of the trenches that were eventually excavated. As anticipated in the *Cultural Resource Investigation Sampling Plan* (The Presidio Trust 2005), the lengths, orientations, depths, and number of trenches required modification once the below surface condition was revealed. The additional exposures were excavated to capture data were required to interpret the stratigraphy and resources encountered in the two planned trenches, and to further define debris fills encountered in the two planned trenches, and to further define debris fills encountered by those trenches.

The trenches were excavated with a conventional backhoe equipped with a 24-inch bucket with three teeth or a 24-inch bucket with a toothless cutting blade ("butter-bar"), the latter employed in circumstances requiring a cleaner cut. Fieldwork for Phase 3 began in May 2, 2005, and continued through May 6, 2005. All trench excavation was continuously monitored by a minimum of two cultural resource specialists.

Discussion of Results

Each of the trenches, 4, 5, and E, are shown relative to the overall project area on Figure 39; Subappendix D-A12 provides a schematic of the relationship among the trenches, Battery West Magazine 21, and the mortar platform and related earthwork. Subappendices D-A8 through D-A10 are soil profiles for each of the trenches. The subsurface stratigraphy in the area is somewhat less complex relative to the stratigraphy encountered in the parking lot adjacent to Battery Godfrey. Visible evidence of the construction of the mortar barbettes and the subsequent modifications related to the construction of the Endicott Era fortifications are clearly represented (Attachment 1: Overlays 6, 7, and 8). Post-Endicott modifications resulted in the removal and capping of the earthworks representing the Battery West era parapet, and substantial portions of filling related to the Endicott modifications to the topography.

Trench 4. Trench 4 was excavated to determine whether portions of the 1870s mortar platform, elements of Battery West, were present and to evaluate the nature of the fill exposed at the surface near the edge of the bluff. The trench was excavated essentially east to west, in two stages. A substantial layer of clay fill (2-3½ feet) was exposed atop a layer of chert fill (6 to 18 inches in depth) that was similar to that exposed in the Battery Godfrey parking area. Two roadbeds were exposed within or atop the chert layer.

On the eastern end of the trench the chert rested atop a silt layer 6 to 24 inches in depth, mixed with a yellow-brown clay. The silt layer sat immediately above a layer of sand, approximately 6 inches thick, which rested on a serpentinite-derived clay layer that was naturally occurring. At the western end of the sand layer, an introduced block of clay fill sat above the sand and beneath the silt fill. West of this activity the trench revealed a continuous layer of clay and a thin lens of "clay fill" beneath the chert layer and above the naturally occurring soil units. Subsequent evaluation of the sand layer that was observed at approximately 7 feet beneath the existing ground surface indicated that it was a portion of the mortar pad construction; a description and discussion of this feature, and the surrounding stratigraphy follows.

Trench E. Trench E was excavated parallel to Trench 4 approximately 45 feet to the north. Trending east-west the trench was approximately 86 feet long and extended west from the historically recorded area of the mortar platforms towards the bluff. A substantial layer of gravel fill/mixed clay fill +/- 4 feet in depth, similar to that exposed in Trench 4, was exposed above the same chert layer; a concrete pad thought to be related to the incinerator once located in this area was exposed, adjacent to the chert bedding. The fill west of the slab consisted of a dark silt layer at a depth of approximately 14 feet resting directly on naturally occurring serpentinite; the silt layer was capped by 2 to 4 feet of sand, a layer of debris fill, and a mixed clay fill with pockets of cobbles and sand.

East of the concrete pad (See Subppendix D-A10 and Attachment 1: Overlay 8) beneath the chert bedding was a shallow layer of sand resting on a 2- to 4-foot layer of silt similar to that exposed in Trench 4. At approximately 7 feet below the existing ground surface a 6-inch sand layer was encountered. The sand layer rested immediately above a clay layer also identical to that exposed in Trench 4. The stratigraphic relationship of the sand to the clay soil unit below, the silt fill above, and the depth of the sand layer suggests that it also was related to one of the mortar platforms. Unlike the sand layer exposed in Trench 4, the western end of this layer appears to have been graded away, along with the underlying clay substrate, and capped soon after by the silt described above (See Subappendix D-A10).

Trench 5. Trench 5 was excavated primarily to define the relationship of the fill in the bluff-top swale south and adjacent to the southern slope of Magazine 21 (Subappendix D-A12), the earthworks that historically formed the south-facing slope of Magazine 21, and the earthen parapet seaward of the mortar platforms. This trench revealed stratigraphy adjacent to the magazine structure similar to that observed at Magazines 27 and 28 (Subappendix D-A9).

The soil layer immediately adjacent to the structure of the magazine is predominately a dark, in this case sandy material that is interbedded with a mixed clay fill layer beneath a minimal layer of topsoil. The mixed clay fill soil unit likely represents the same importation and placement of soil undertaken in the Endicott construction period that was intended to mask the profile of the magazines.

Below the mixed clay fill, at depths of 7 to 8 feet, a substantial accumulation of broken brick was encountered within a soil unit comprised primarily of silts (Subappendix D-A9). The lack of any mortar adhered to or in association with the brick sampled from this deposit strongly suggests that it represents waste brick from the magazine's construction. The waste brick appears to have been mixed with imported soil and used to form a portion of the earthen parapet that extended southeast from the south-facing slope of Magazine 21, further suggesting that the historic construction grade was likely the interface of the lower silt layer.

At a point approximately 20 feet south of the top of the magazine it appears as though the mixed clay fill and silt soils thought to represent a portion of the parapet were graded away to produce a level area suitable for the concrete slab and adjacent sand apron. Both layers were subsequently buried beneath 2 to 3 feet of fill. A stratum of red chert beneath the sand apron and silt layer (see Attachment 1: Overlay 7), appears anomalous, owing to its position beneath the silt layer. However, the trench was not accessed (owing to its depth) to prepare this profile, and it is possible that the chert is related to an intrusive event that was not observed in the sidewall.

Magazine 21 Entrance Exposure. The entrance to Magazine 21 was cleared to enable access to the interior for condition assessment, including a structural evaluation, as well to evaluate the relationship of the fill to the structure. The backhoe was employed to remove the bulk of the fill and hand tools were used to complete the clearing. This task revealed a granite threshold and entrance stairway leading down to the doorway of the magazine (Figure 42). The concrete balusters to each side of the stairway were found to be essentially intact with exception of slight scaring by the equipment that was used to fill the entrance. The door to the magazine was absent, but two damaged hinge-pintles were visible on the eastern side of the doorway.

FIGURE 42: Entrance to Magazine 21

The elevation of the threshold stone at the top of the entrance to Magazine 21 was found to be 215.63 feet, when corrected to the 1893 elevations, which places it approximately 1.3 feet above the historically recorded and observable elevation of the sand layer on which the mortar platforms are thought to have rested.

Mortar Pit Excavation

Close inspection of the sand layer in Trench 4 revealed a stratum consisting of deteriorated redwood, and the remains of iron fasteners in an advanced state of deterioration, resting on top of the sand layer and capped by the silt layer described above. To evaluate the stratum and the possibility that it might be the remains of a mortar platform, the trench was laid back on each side to the extent of the sand layer (revealed in the trench profile) and to the depth of the interface. This action produced a large aerial exposure 15.5 feet north-south by 15 feet east-west. Limitations on space required the backfilling of Trench E, a circumstance that subsequently

obviated the opportunity to confirm that the sand layer observed there also represented a mortar platform.

Archaeologists monitored the backhoe-assisted removal of the fill layer. No chronologically sensitive artifacts that would provide a date for the fill were observed. Hand excavation was employed to remove the remaining fill resting directly on the wood and metal remains. Other than a flat, black-rubber seal (4½ inches in diameter) found at the interface between the sand and silt layers–obviating an association to either of the strata–no artifacts beyond the corroded metal were observed.

Figure 43 provides a plan and profile of the completed excavation. The sand layer, 1 foot northeast by southeast and 13 feet northwest by southwest was contained within a shallow depression that had been excavated into the clay substrate. Portions of the substrate appear to have served as "curbs" along the sides to retain or revet the wood platform built upon the sand that supported the mortar. The corrected elevation of the deteriorated wood remains on the surface of the sand is 214.03 feet; as indicated in the 1870 map of West Battery, the contour elevation immediately west of the mortar platforms at the based of the parapet was 213 feet.

As noted above, removal of the silt layer exposed little more that a veneer redwood, which varied in width from 3 to 4 inches and contained no more than 8 fasteners, some that appear to be short, squat flat head wood screws, in an extremely deteriorated condition. The silt removal and subsequent investigation of the stratum characterized by the wood and metal remains did not yield any chronologically sensitive artifacts that would indicate dates of construction, use dates, or confirm the date that the silt fill was placed above the sand.

However, the consistency of the silt fill, its color, and stratigraphic position suggest that it represents the displaced earthworks that were part of the original fill above the magazines.

The mixed clay soil unit seen at the western end of the sand layer in Subappendix D-A8, as observed in the north wall profile of Trench 4, was not observed in the southern wall profile of the aerial exposure, suggesting that it may have been a portion of the parapet graded on top of the sand layer during the Endicott modifications discussed above.

The section drawings included as an inset in the 1870 drawing of Battery West are of some interest in this regard. The section Drawing "F.1" was drawn through the mortar platform thought to be immediately adjacent to the north of the platform revealed by the excavation. The profile (Figure 43) depicts a platform-like square approximately 7 feet long resting on an elevated level area that is above a line designated as "Natural Surface." The elevation above that line is approximately 1/2 foot. The width of the level area is shown as 30 feet; and the increase in elevation to the peak of the parapet is approximately 9 feet. The entire earthwork that comprises the parapet appears to have been constructed on the line noted as "Natural Surface." The elevation difference between the level area and the base of the "covered way" is 5 feet.

2.4.2.5 A Discussion of Battery West and Endicott Era Fortifications and Related Earthworks, Their Preservation, and Relationship to Post-Endicott Disturbance

Data obtained from an extensive review of historic documentation and a subsurface field investigation provide considerable evidence that previously unknown elements of the West Battery fortifications and related earthworks, as well as remnants of the Endicott Era earthworks have been preserved in the archaeological record. In some cases, as with the mortar platform, the archaeological evidence lends itself to immediate and relatively straightforward interpretation. However, in other cases individual soil units lack materials that are sufficiently chronologically sensitive, or are situated in such an ambiguous manner that placement relative to the developmental history of the project area is very difficult to achieve. Extrapolation with respect to the presence/absence of soil units representing the earthworks related to each of the two major building episodes, on the basis of the data collected, is particularly difficult in light of the extensive post-Endicott Era modifications to the project area.

Observations and data obtained from geologic test pitting combined with data from the subsurface archaeological investigation have been used to characterize and to project the location of post-Endicott Era landfills throughout the project area. For the most part these landfills are situated on the west-facing slopes of the bluff; however, the archaeological investigation identified significant fill deposits and related landscape modification in BBDA 1 south and west of Magazine 21, and north and west of Magazine 28 at BBDA 2.

The relationship of post-Endicott Era landfills and the structural remains of both West Battery and the Endicott Era fortifications, that is, the actual physical structures, are easier, as would be expected, to define than the juxtaposition of the landfills and the earthworks related to each period of fortification. In no case were landfill materials observed in contact with the structural remains of fortifications, that is, the concrete and brick structures.

The remains of the four mortar platforms and related parapet between Magazines 21 and 22 (BBDA 1) are buried beneath Endicott Era and Post-Endicott Era fill. Two of the mortar platforms evidenced by sand deposits, which appear to have been the foundations for the wooden mortar platforms, were revealed during the field investigation. Portions of the parapet, albeit truncated by post-Endicott Era grading, and the remnants of the frontal slope were observed in Trench 4. Excavation for the two incinerators and appurtenant features built circa 1922 and 1934, the latter replacing the former, appear to have destroyed the earthworks to the north and west as revealed by Trenches E and 5. The remnants of the earthworks, revealed in Trench 4 are capped by a layer of chert representing the roadbed and base associated with one or both of the incinerators.

With respect to the juxtaposition of the landfills and the earthworks at BBDA 2 a waste fill (a concrete washout in this case identified as artificial fill waste) located to the north of Magazine 28 appears to have been deposited on a cut surface that removed the Endicott Era earthworks and any vestiges of the West Battery earthworks; the relationship of the waste fill to the earthworks on the western side was not evaluated in the field. A remnant of the clay layer thought to represent the “sodding layer” related to West Battery construction and the fill thought to represent the Endicott modification of the associated earthworks was observed some 40 feet northwest of the magazine at a depth of 6 to 7 feet.

Reference to the profile for Trench 2 illustrates a distinct layer of clay thought to represent the "sodded" surface of the frontal slope, trending downward towards the bluff, that is topped in one area with what is thought to be Endicott Era fill. Trenches A, B, and C expose a similar layer at a depth of 7 to 8 feet, and the layer was exposed throughout Trench 2 at a depth of 7 to 10 feet. The consistent presence of this layer, as evidenced in Trenches 2, 3, and A-C, suggests that substantial portions of the West Battery "sodded" frontal slope may remain buried beneath what is presently the parking area in front of Battery Godfrey.

The absence of soil units that represent the West Battery/Endicott Era earthworks between Magazines 27 and 28 are likely the result of a wholesale landscape modification that occurred during and subsequent to the Endicott construction phase.

The modifications leading to the present condition may have been sequenced as follows. That the West Battery earthworks "the parapets, superior slope and glacis" related to these positions was completed seems to be confirmed by the 1898 plan of Fort Point (see Rodman Emplacements, this report). Endicott Era construction is reported to have buried the gun positions between Traverses 27 and 28 and to have included the construction of a "parados" (an elevated landform) on the southern end of the battery to prevent enfilade fire. The "parados" subsequently became a vehicle access route to a bluff-side dump area.

The modification that removed the West Battery earthworks and downcut to the natural soil horizon may have been a cut-and-fill episode related to the 1890s construction of the "parados." The cut surfaces identified in Trench Profiles 1 and 2, adjacent the magazines, and mid-way along the trenches may be related to the cutting and filling required to build the "parados." Perhaps the chert base or road bed B atop the sand fill exposed in each trench represented a prepared surface enabling access to the dumpsite.

It then appears that a subsequent episode of grading, almost certainly in the 20th century removed a portion of the "parados" and that cut was then in-filled with waste concrete and debris. The relationship of this cutting and subsequent filling to the surfacing of the area with the chert base or road bed A was not determined.

In summary, the most visible remains of West Battery are the entries and transverse earthworks that housed magazines. Today, these earthworks are for the most part incorporated into the structure of the latter Endicott Era Batteries. At BBDA 1 Magazine 21 was incorporated into the southern flank of Battery Marcus Miller after significant reduction in height, but with no apparent modification to the entry. Magazine 22 was incorporated into the northern flank of Battery Boutelle; modification of the height is unclear, and a new entry was constructed. At BBDA 2 Magazine 27 was incorporated into the southern flank of Battery Godfrey; here again the earthworks above the magazine were reduced, but the entry appears to be the original construction. The earthwork over Magazine 28 was also reduced in height; however, the filling of soil–presumably as part of the parados construction on the northern side of the magazine–in conjunction with reduction in elevation tends to make the magazine appear very indescript when viewed from the parking lot area.

At BBDA 1, the open area between Magazines 21 and 22 is the result of modifications to accommodate the Endicott Era construction followed by cutting and filling in preparation for subsequent construction. Subsurface investigation of the flat indicates that earthworks for at least two of the pads that supported mortar platforms, and evidence of the wooden platforms, remain buried beneath the surface. Assuming similar preservation it is very likely that remains of the

other two platforms have been preserved as well. A truncated portion of the earthen parapet also remains, but subsequent grading appears to have destroyed the frontal slope. This archaeological evidence confirms the historic reference to the completion of construction in this area, but provided no information on use or abandonment.

At BBDA 2, a section of the parapet, albeit breeched, appears to remain between Magazines 28 and 29, although it has been removed in the Battery Godfrey vicinity. Again, its removal was probably related to the construction of the parados, which buried elements of the frontal slope in the parking area in front of Battery Godfrey.

The covered way that links each battery on the eastern side appears to have been substantially altered from its original design. The rear or reverse slope of the covered way appears to have been from 2 to 5 feet in height above the base of the road bed when first built, the current condition has heights twice or more, indicating the introduction of significant amounts of fill.

2.4.3 Area of Potential effects Expansion – Merchant Road

Modification to the APE to accommodate the relocation of Merchant Road required additional background research, field survey, and evaluation. The NPS noted that additional historic batteries, roads, vegetation, and possibly other features may be located within the expanded APE area.

On February 3, 2005, Michael Land of the Presidio Trust provided George Ford, Manager, Remedial Construction of the Presidio Trust with a memorandum entitled, "Merchant Road Tree Island Building History" (See Appendix F for memorandum). This memorandum summarized Lamb's findings of his investigation on the past uses of the buildings that existed in and around the area referred to as the "tree island," between Merchant Road and Lincoln Boulevard. Working with maps and Quartermaster Reports available to the Presidio Trust, it is speculated that two small structures that appear in the 1907 Harts plan may have been a guard shack or sentry post, based on their location to roads. Seeing the larger building referenced as the Guardhouse in the *Defender of the Gate* only added to the speculation.

In the Fort Winfield Scott Lighting System map of 1917, two buildings (80 and 49) are located in the tree island area, as well as several unnumbered buildings west of Merchant Road. Buildings 70 through 78 and 136 through 143 are present east of Lincoln. In the *Presidio Archaeological Resources* (draft) by W.H. Adams (1994) Building 80 is referenced as being in association with the 7th Company Artillery Cantonment and is labeled as "MILITA WH." Building 49 appears to have survived into the future, possibly as late as 1951, when it was known as Building 1394 and then 1659. Buildings 70 through 78 were identified as being constructed in 1917 and used for a Camp of Instruction (Adams 1994). The final plan image in 1943 shows a number of structures in the now expanded tree island area. None of the buildings are identified.

2.4.3.1 Merchant Road Cursory Survey

A reconnaissance-level survey conducted in the Merchant Road realignment vicinity encountered extremely dense vegetation. Observation of the ground surface was all but totally obscured by the unmaintained vegetative growth.

A subsequent inspection was made on May 6, 2005, when geotechnical test pits for the Merchant Road realignment were undertaken. Test Pits B and C were excavated to a depth of 5 feet. Each

revealed a 2-foot layer of topsoil above the underlying Colma formation. The third test pit revealed a layer of red chert approximately 2 feet beneath the ground surface. This red chert layer may be evidence of an earlier road or parking area. Given the depth of the discovery, no further pedestrian survey for the road alignment was undertaken. No other archaeological features or artifacts were observed.

2.4.3.2 Covered Way Test Pitting

Three test pits, essentially trenches, were excavated along the covered way to corroborate the impression derived from historic documentation that fill placement/disposal had significantly altered the appearance of the covered way in the project area. Both BB1TP110 Test Pits 111 and 113 exposed 6 to 7 feet of fill consisting primarily of redeposited Colma formation materials. However, chert bedding was observed in Test Pits 111 and 113, and a cobble fill layer was encountered in Test Pit 110. The presence of this fill in conjunction with the fill observed adjacent to the covered way at the site of the mortar pit excavation (see Section 2.4.2.3) suggests that the present day appearance of the covered way, particularly with respect to its depth relative to the slopes that are found on either side of the road way, may have been significantly exaggerated by the placement of the fill.

3.1 MITIGATION PLANNING – END CONDITION

Removal of debris and waste material from the disposal areas along the Baker Beach bluff will inevitably result in modifications to the present landscape. In the paragraphs that follow summary statements regarding the fill to be removed are followed by descriptions of an end-condition that would conserve the historic landscape and provide the visitor to the bluff a sense of place consistent with the heritage resources located there.

BBDA 1A

BBDA 1A – Located on coastal slope west of north end of Battery Marcus Miller.

The material that will be removed consists of a shallow layer of discarded roofing material that was removed from Battery Marcus Miller. The materials are located in the area that was historically the frontal slope of Battery Marcus Miller and the natural slope that extends westward from the battery complex. Following removal of the roofing material and related debris the surface will be re-configured to conform to the existing gradient of the frontal slope of Battery Marcus Miller, or to the natural landform. The foot trail will be redefined through the areas of remediation. Monitoring by a qualified archaeologist is recommended to ensure preservation of any remnants of the former frontal slope.

BBDA 1

BBDA 1 – This disposal area is located between Batteries Marcus Miller and Boutelle in the area that was the former location of West Battery mortar pits XLV - XLII. The area is bound on the north by Magazine 21 and on the south by Magazine 22, the covered-way to the east and the shoreline to the west. The area of historical interest is located between the two magazines and westward from the covered way to the edge of the bluff.

Removal of the fill from the west-facing slope, poses no immediate adverse effect to the resources identified on the bluff above the fill area. Concerns regarding slope stability and related potential effects to Battery Boutelle are recognized, and instrumentation will be placed at Battery Boutelle during remediation activities to provide substantial and comprehensive data with respect to any changes in the existing condition.

On the bluff top in the historic location of the mortar platforms, parapet, and frontal slope, fill soils will be removed to a depth consistent with the chert layer that for the most part blankets the entire site. This layer is thought to be sufficiently thick and/or is located high enough above the resource, to act as a protective cap to the original construction and landforms that comprise this section of the fortification.

In the vicinity of the incinerators, on the western margin of the area adjacent the bluff, excavation to remove contaminated soils, where the chert layer was not encountered, may require removal of a portion of the earthworks related to Magazine 21 and the frontal slope. Monitoring will be required during all soil removal to ensure that no undue damage accrues to the earthworks.

The end condition will involve reconfiguring of the ground surface in a manner that conforms to, or reflects, the topography recorded in the 1902 plans of the “Battery Commander Station for

Battery Cranston" (Figure 44). That plan appears to reflect the post-Endicott modifications to the surrounding earthworks but retains the bench that was the location of the mortars, the parapet and the frontal slope characteristic of the West Battery period. Elevations provided by the drawing correspond relatively well to the existing condition, in that the upper most surface of Magazine 21 is shown as 222 feet, and the elevation of that feature was recorded during the 2005 field investigation as being 220 feet. Reconfiguration of the existing landform will look to restoring the parapet and frontal slope in the vicinity of the mortar platforms between Magazines 21 and 22.

Some in-field effort also will be required to create conformance of the grades in the vicinity of the granite threshold stone at the entrance of Magazine 21 and the four mortar pit locations to the south of the magazine.

It is recommended that trained archaeologists monitor the remediation and reconfiguration activities to ensure that the expected subsurface condition is consistent with the profiles revealed during the test phase and that no damage accrues to unanticipated resources.

BBDA 2A

BBDA 2A – This remediation area is located on the coastal slope toward the middle of Battery Godfrey. Remediation activities in this area are not anticipated to have any adverse effect on the resources located on the bluff top.

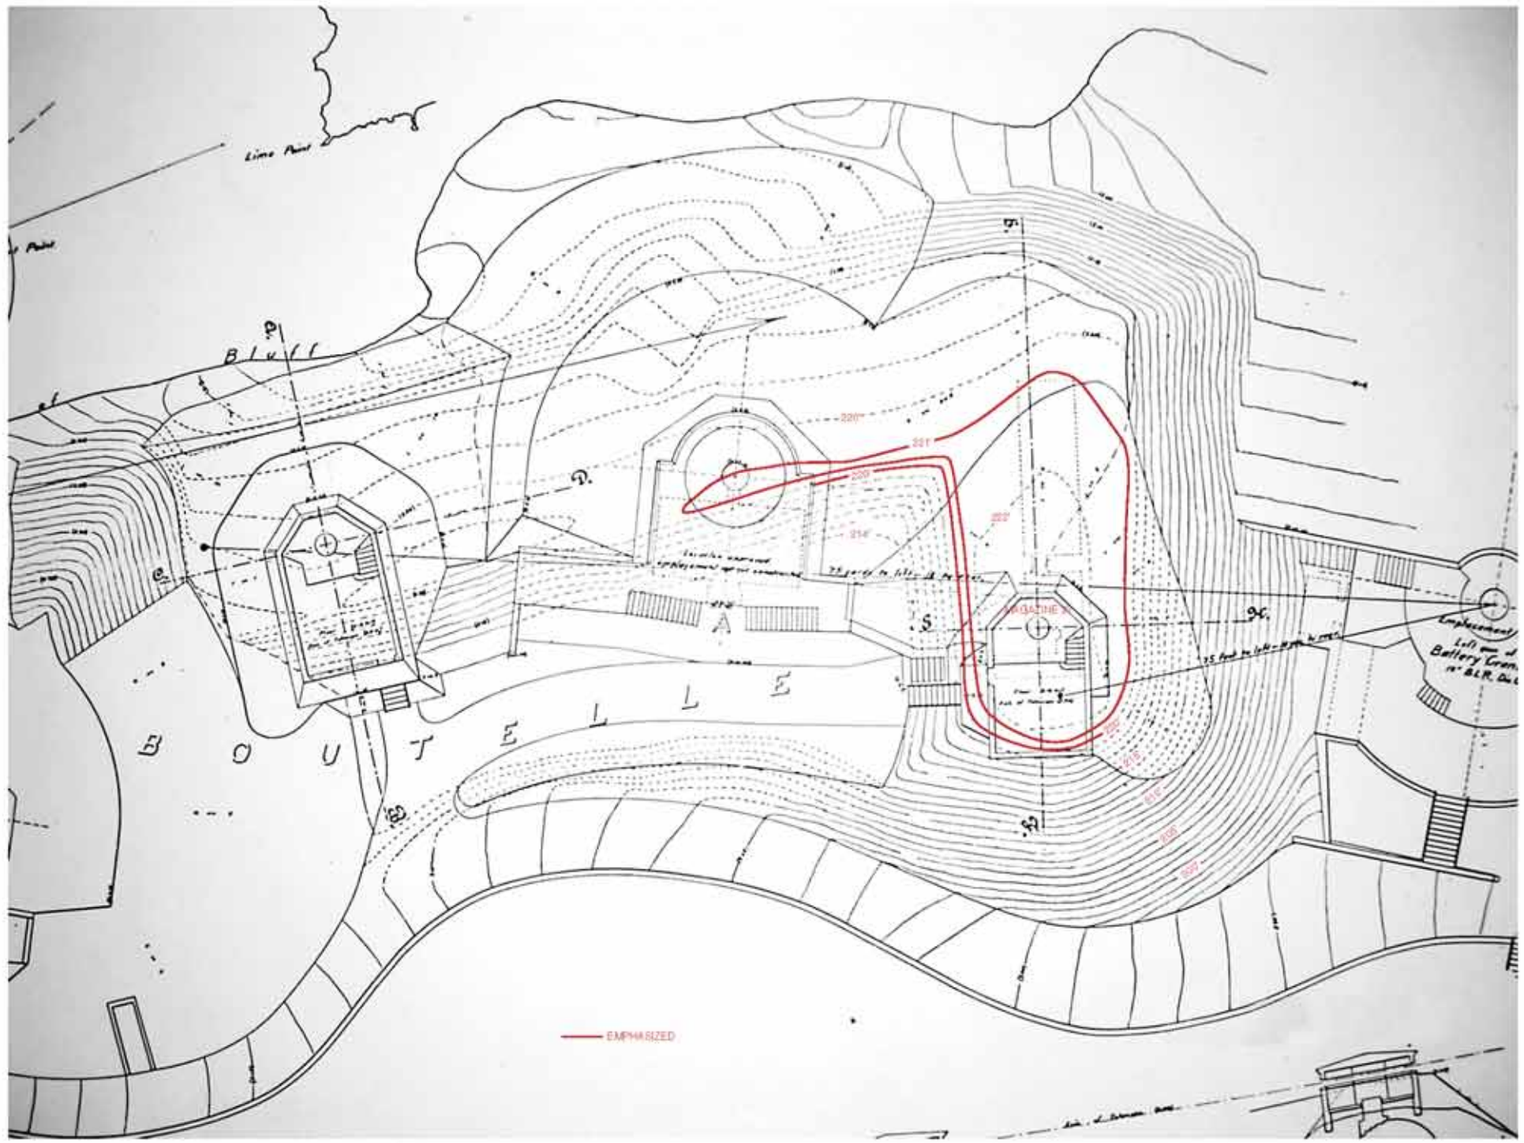
BBDA 2

BBDA 2 – This remediation area is located at the south end of Battery Godfrey, essentially between Magazines 28 and 29 and extends north into the existing parking lot, and west, to and over the bluff. Based on the profiles revealed during the testing conducted in mid-2005, the removal of the waste fill will have no impact to the remaining historic resources in the vicinity.

Evidence of the frontal slope (specific identification as to whether this is associated with the Battery West fortifications or the subsequent Endicott Period fortifications has not been established) has been identified in the parking lot area (see prior discussion and profile drawings). Pending resolution of the disposition of the parking lot and general planning issues, consideration should be given to re-configuring that area to conform to the historic gradient consistent with the frontal slope of the Endicott period fortifications.

3.2 LANDSCAPE CONSIDERATIONS

The concrete fortifications and man-made earthworks that parallel the west-facing coastal bluffs, south of the Golden Gate Bridge, contrast strongly with the otherwise natural appearance of the surrounding environment. The cultural landscape, embodied in the concrete structures, the spatial organization of the structures, the roadway that served to safely connect them, and the earthworks that enveloped and camouflaged all evoke a period of time when concerns for national defense and the contemporary modes of warfare required the construction of such fortifications. Formally designed by military engineers and strategists during the 19th century, the cultural landscape capitalizes on the geography of the bluffs, which provide an elevated position for artillery while also providing the opportunity for concealment of the related fortifications.



Taken from Battery Commander Station for Battery Cranston, U.S. Engineer Office, San Francisco, 1902.

URS	26814549.SUPRE Baker Beach Cultural Landscape	Post-Endicott Period Topography in the Vicinity of Magazines 27 and 28	Figure 44

Spatial organization, dictated primarily by the need for a clear, designated field of fire and the logistics of supply, placed the batteries side by side along the top of the bluff. The two primary periods of construction differ somewhat in this regard. In the project area the Endicott Era (1891-1904) concrete fortifications dominate the landscape, with Battery Marcus Miller on the north, followed by Battery Boutelle, and Battery Godfrey on the south. These batteries–comprised of gun platforms, magazines, and control centers–form discrete, individual complexes at strategic intervals. A reliance on concrete and steel, their spatial organization, and the effort to make them less obtrusive to the landscape are characteristics of the Endicott Era fortifications, which reflects not only a shift in material and construction technology consistent with the times, but also speaks of newer warfare technologies emerging in the late 19th century.

West Battery (1870-1876), on the other hand, is evinced by the presence of earthworks among and surrounding the Endicott Era batteries. These earthworks, when originally constructed–and their superior slopes, parapet crests, and transverse magazines–formed a continuous chain of defense along the edge of the bluff that was imposed upon the natural topography. Relying primarily on earth-covered brick and concrete, their remains are a final vestigial expression of siege defenses common in the mid-19th and earlier centuries.

The covered way now serves as a broad trail (Bowman Road) linking the Endicott Era batteries, but its route appears to reflect elements defined in both the 1870s and 1890s. In places the roadway becomes serpentine, dictated perhaps by the placement of the West Battery fortifications. Other sections of the "covered way" seem to reflect the measures taken in the Endicott Era to conceal its presence.

Numerous informal foot-trails, extending east to west from the parking area along Merchant Road, provide visitor access and exploration of the structures and to take advantage of the expansive view provided from the location of the individual batteries. These footpaths are not visible on historic period photographs and are assumed to have emerged sometime after the Army's formal use of the area.

The subject fortifications have been abandoned and more or less neglected since at least 1946. The advanced deterioration of the iron fixtures, spalling of concrete, and dense vegetation that surrounds and masks the landforms related to the batteries is advanced in some areas. Vegetation on the batteries is comprised almost entirely of introduced species, the most dominant being ice plant, and including cypress trees, blackberry and other shrubs, serve to obscure the man-made earthworks that were in turn intended to both camouflage and protect the gun platforms and magazines. Natural vegetation consisted of small shrubs, flowering plants, and grasses. Thus, while the dense overgrowth promotes a sense of the mysterious, it in fact reflects the neglect of the area, except on the landforms around Battery Boutelle and Godfrey where NPS rehabilitation projects began in 2001.

As noted in Section 2.0 the remaining elements of West Battery, the majority of which have been incorporated into the Endicott Period fortifications, and the portions of the Endicott Batteries located in the project area, Battery Marcus Miller, Battery Godfrey and Battery Boutelle, are all contributing elements of the Presidio National Historic Landmark. As such, any action that would result in the modification of those resources, that would serve to diminish the characteristics that define the resources as contributing elements is viewed as an adverse effect.

This study was undertaken specifically to identify the potential for such an effect. Substantial research and field investigation was completed to provide a thorough understanding of the resources as they were constructed; and field investigation was undertaken to determine the extent and nature of those resources as they currently exist.

While the present undertaking will ultimately lead to substantial modifications of the existing landscape in the areas to be treated, the proposed end condition will more nearly replicate the historic landscape as it appeared in the post-Endicott construction period of the early 20th Century. In no case were fill units composed of debris or waste materials found to be situated in direct contact with the masonry elements of either the West Battery or Endicott period fortifications.

However, soil units containing debris and other materials that will require removal are in some instances found in direct contact with earthworks related to one or both periods of fortification. Portions of those earthworks may require removal if soil testing, conducted during remediation, demonstrate unacceptable levels of contamination. The net effect of this removal is anticipated be minimal, but cannot be quantified until the extent of contamination is determined. In all cases the landform will be restored with like, clean fill, and the uninformed observer would be unaware of the modification.

Cumulatively, modifications such as these in conjunction with the changes related to successive phases of construction and deterioration as a result of natural causes, e.g., erosion, have resulted in the removal of substantial portions of the original soils imported to construct the earthworks. The current project, by researching the construction history and documenting the present condition provides a baseline by which future conservation and restoration of the resource can be achieved.

United States Army Corps of Engineers Armament Map 1898 Map of West Battery

AS-BUILTS REVIEWED

- Battery Marcus Miller (3 sheets). Handwritten notes on one of the copies of each of the three sheets indicate different measurements/dimensions of a few rooms. Also assigns different numbers to the rooms than what are on the plans. (date? citation?)
- Battery Godfrey. Good copy of sectional plans of Battery Godfrey.
- Battery Boutelle.
- Battery Stotsenburg-McKinnon

All U.S. Army Corps of Engineers "as-builts" for above referenced batteries included several oversized folders of many versions of design plans for Endicott Era batteries. Selections were made to be copied based on completeness of plans, dates of plans/as-builts as compared to actual construction dates of the batteries, and level of detail of the plans.

Report of the Field Exercise
Baker Beach Remediation Project, Archaeological Survey Field Notes

MAY 19, 2004, WEDNESDAY 8AM-10:30AM

A pre-field meeting was held at the Presidio Archaeology Lab (Building 230) on Gorgas Avenue.

Meeting participants: Chris Lee, Vance Benté, and Sean Dexter from URS Corporation, Leo Barker and Hans Barnaal from the NPS, and Megan Wilkinson from the Presidio Trust.

Topics Discussed:

- Level of success achieved from archival research and potential additions to corpus of data.
- Digitization of maps and as-builts: how much has been achieved? How much more is necessary?

Hans states that he needs this field exercise to complete the mapping of the Endicott Era batteries, and to position the 1898 digitized as-built of West Battery elements into real space.

Leo Barker produced a set of three historic aerial photos from 1942 that we used as comparison with the high-resolution aerial photos taken of the Presidio in 2000. These images were then used in conjunction with modern and historic maps (both topographic and feature-based maps) to locate features that could contain remnant elements of West Battery.

It is known that certain magazines from West Battery were incorporated into the Endicott Era batteries such as Batteries Godfrey, Boutelle, and Marcus Miller, but the extent of reuse must be explored through pedestrian reconnaissance and then digitally mapped with a Total Station. These data will be compared with CAD and GIS maps digitized by Hans from the as-builts of the Endicott batteries and historic maps of West Battery.

Subjecting these features to "ground truthing" and surveying for additional, previously unrecorded/mapped extant features of West Battery is a top priority of this field exercise to better inform an "opportunity and constraints analysis" for the remediation project.

Goals of Field Survey:

- Locate all remnant elements of West Battery, and previously unrecorded features
- Agree upon the location/route of the "Covered Way" (the pathway that wound between the fortified earthworks and batteries of the coastal fortifications).
- Digitally map with the West and Endicott Era structures that are within the current project's Area of Potential effects (APE).
- Through the field survey, translate findings into a statement that describes physical limitations on the usage of heavy equipment in the APE that could adversely affect historic features of the subject coastal fortifications.

10:30 – 12:00 Noon, Field Survey

Early focus was on two West Battery magazines (#28-29) south of Battery Godfrey, the southern terminus of the project's APE. Historic maps and other documents such as the Army Corps' "Letters of Completion" numbered the magazines of West Battery sequentially. Remnants of five West Battery magazines were located today, including the two previously mentioned at the southern terminus of the project south of Battery Godfrey.

12:30 – 5:00PM

The two southern West Battery magazines were mapped by Hans and Megan at the end of the day. Leo and Vance collaborated on "ground-truthing" elements of the historic photos and maps to see if they could locate features of batteries.

During the early afternoon, Leo noticed that a door had been taken off its hinges at the northern end of Battery Godfrey. Although there was concern that the removed door could provide access to vandals and homeless people it did provide access to the archaeologists. Upon entry, it became apparent that the anteroom was part of the Endicott Era construction evidenced by the reinforced concrete, but that a much larger room led off at the right (northern) side of the anteroom. Preliminary investigation on Day 1 of the survey showed that a brick-lined passageway led down a short flight of stairs to a hallway. This hallway then turned to the left and led into a small room with another door at its far end. This doorway led into a long, rectangular room. Measurements of these rooms and passageways will wait until Day 2 of the survey. Comparison with historic records demonstrated that the West Battery magazine found opened at Battery Godfrey is of the same design as buried West Battery Magazine 21 adjacent to Battery Marcus Miller. Data collected helped to inform some of the nature of what is expected in the area of the BBDA 1 crane pad and haul road location.

A partially buried feature of unknown origin and purpose was discovered between West Battery's Magazines 28 and 29 at the end of the day. It consists of a poured (in individual pie-cut sections) and surfaced, circular concrete pad. It is approximately 12 feet in diameter, with a circular open center approximately 24 inches in diameter. The surface has been painted with a thick coat of rust-colored orange paint similar to the color of the Golden Gate Bridge. Its function is unknown. Another partially visible circular concrete feature was located on the outer slope of West Magazine 29.

By day's end the route/location of the "covered way" was agreed upon by all present after continued verification of features on the historic photos to extant features in the field. Additionally, Park Police were notified that the door had been forcibly removed from the magazine at Battery Godfrey.

MAY 20, 2004, THURSDAY

Field Crew:

- Vance Benté
- Leo Barker
- Chris Lee
- Sean Dexter
- Hans Barnaal

The primary focus of the second day of field survey was to take measurements of the brick-lined magazine at Battery Godfrey, to finish Hans' digital mapping of the Endicott Era batteries, and to further investigate the red ceramic feature at the southern end of the APE.

Upon arrival at the site, Vance Benté and Chris Lee investigated a brick feature protruding through an earthwork emplacement between Batteries Boutelle and Marcus Miller. The feature appeared to be a doorway into a magazine, likely of West Battery, that had been covered in dirt and used to improve the "covered way", but likely not used for its intended purpose as a magazine. The brickwork was identical in shape to that found the previous day at Battery Godfrey. It was decided that both this brick feature and the rooms/passageways discovered the previous day were magazines of the former West Battery. The one at Battery Godfrey had been incorporated into the Endicott Era system as a magazine while the feature that was investigated on Day 2 was covered over and used, not as a magazine, but, was incorporated as part of the "covered way" to shield the Endicott batteries from view from the sea.

Leo Barker and Chris Lee took extensive measurements of the West Battery magazine that was incorporated into Battery Godfrey. All of the rooms were measured as well as the stairwell, steps, wall thickness, ceiling height, etc.

Hans continued to take Total Station "points" with the assistance of Sean Dexter.

At the end of the day it was decided by the survey participants that the majority of exploratory work had been accomplished and that a third day would be required to complete the data collection with the Total Station, but that this task would be accomplished by NPS employees, Leo Barker and Hans Barnaal, and that URS would not be required to participate in the third day of fieldwork.

Compilation of data used in preparing historic context

REPORT OF SUBSEQUENT SHORELINE SURVEY

October 4, 2005, Tuesday 12:00PM-1:10PM

At 12:00 pm Henke and St. Clair walked to the beach areas below Test Areas 1 and 2A to investigate and record the debris in the area. Henke informed St. Clair that there are pictures

documenting much of the rubble from a previous MACTEC report. Henke told St. Clair that she would provide these pictures to St. Clair for use in the cultural resources report. Henke also took several digital photographs of debris that St. Clair pointed out as potentially important.

Overall, more concrete and metal debris appeared to be concentrated along the beach below test area 1 versus test area 2A. Henke did note that the sand level had increased since the time that MACTEC had conducted their initial survey in the spring. Below test area 2A, along the beach, various fragments of both water-worn and unworn concrete were noted. The concrete contained different types of aggregate, including one that had primarily Franciscan-derived minerals, another primarily made of red chert, and another with mostly rounded river cobbles. Also observed along the hillside below test area 2A was a spool of cable or wire that Henke noted had fallen further down the hillside during investigative activities using the Spider Excavator earlier in the spring.

On the beach below test area 1, a much higher concentration of concrete debris was observed. Two chimney fragments were noted, including one made primarily of firebricks, and another made of red brick. The firebricks had maker's marks from [RICHMOND], [STAR M.S. DICKEY CLAY MFG. CO], and [GMB] in an oval with [COLUMBIA] also written on the 'GMB' brick. Concrete footings observed included some with cut-out areas where fence posts may have been placed, areas where corroded metal pipes were eroding out, and concrete pieces that looked to function as things such as gutters. Concrete in this area contained various types of aggregates that could be representative of different periods of construction. The aggregates included (1) Sandstone aggregate, (2) Red Chert aggregate, (3) an aggregate that contained more rounded and even-sized stones, (4) an aggregate that contained more angular pieces, and (5) an aggregate that contained a Franciscan mix of red chert, green chert, etc. A couple of pieces of cut granite were observed. Various metal pieces were noted, including metal spikes, metal bolts, a possible metal rudder to a boat, and two large metal axles. Of interest was a metal piece of machinery that may have been some type of pressure gauge? A large piece of slag was observed that contained melted pieces of glass and metal. Perhaps the slag came from the incinerator that was perched above the cliffs in test area 1 historically? Another interesting piece of debris noted was a large square piece of cement with board mold marks still visible. The cement was molded into four equal compartments. Pieces of wood that may have previously been used as fence posts or beams were also noted in the vicinity. Many of the pieces of wood have been deteriorated from the saltwater and waves. One large beam contained corroded metal pipes and may have been related to a structural element of a building.

Overall, the materials and debris observed along the beach in these areas appear to be related to structural elements, although it is unclear what structure. Further research into the types of materials used on specific batteries and related structures in the area that have been demolished would be helpful.

The beach survey was concluded at 1:00 pm. St. Clair left the work site at 1:10 pm.

Appendix B

Monitoring Notes: Vegetation Removal, Geotechnical Test Pitting, and Archaeological Investigations

Baker Beach Disturbed Areas

Cultural Resources Investigation

Brush/Tree Removal

Daily Field Notes

Monday, February 14, 2005 - Today was the first day of brush and tree removal at the Baker Beach Disturbed Areas. An initial team meeting and de-briefing of Marin County Arborists work crew was planned for the morning. Those present at the meeting included: Vance Benté (URS), Michelle St. Clair (URS), Leo Barker (NPS), George Ford (Presidio Trust), Ken ? (Marin County Arborists), Craig Benson and various laborers from Marin County Arborists.

Barker outlined protocol for retrieval of artifacts, as well as the process should buried remains or unexploded ordinance be encountered.

1) All materials (including any modern material like bottles, aluminum cans, etc.) should be collected during the brush clearing and tree removal process by the work crew. All materials will be placed in labeled buckets provided by the NPS. Buckets will be collected by URS staff at the end of the workday and transported to the NPS/Presidio Trust Archaeology Laboratory for review by URS and NPS staff.
2) If human remains or unexploded ordinance is encountered during the brush clearing and tree removal process, Leo Barker (415-561-4836) and George Ford (415-561-4292) should be immediately notified by phone. Immediately following, Park Dispatch (415-561-5505) should be contacted.
3) If there is any person(s) in the area that become a nuisance to the work crew, the Park Police (415-561-5656) should be contacted.

The work crew began to work at approximately 9:30 am. Michelle St. Clair, Craig Benson, and David Thompson stayed at the site to monitor work. Work was concentrated in the low-lying area between Battery Boutelle and Battery Miller. Weed-whackers and chain saws were used to clear tall grass and bushes. The crew also began to remove cypress trees located near Battery Miller. It began to rain heavily at approximately 11:00 am. The crew works in the rain. The crew took a break for lunch at approximately 12:30 pm. Work resumed at approximately 1:15pm. It continued to rain heavily throughout the afternoon.

At approximately 2:00 pm, St. Clair left the site to take collected items to Leo Barker at the NPS/ Presidio Trust Archaeology Laboratory for review. Items included: modern glass bottles, aluminum cans, a pair of plastic sunglasses, and a sunglass case with a hypodermic needle kit for either drug use or insulin. St. Clair returned to the work site with additional buckets and monitored the crew's activities until clean up at 4:00 pm.

Tuesday, February 15, 2005 - St. Clair arrived at work site at 8:00 am. It was raining moderately. St. Clair waited for Marin County Arborists work crew until 8:30 am. Crew did not show up. St. Clair left a voicemail message for George Ford. St. Clair returned to the URS Oakland office. Ford contacted St. Clair at approximately 10:30 am and explained that the brush clearing and tree removal work was called off for the day. Concerns over safety and protections

of the batteries in the rain were voiced. Ford had informed the Marin County Arborists work crew (including Ken) that they should stay off the slopes and avoid clearing trees off the batteries when it was raining. It was decided that conditions were too wet and saturated to proceed on Tuesday. St. Clair and Ford agreed to speak Wednesday morning concerning the work schedule.

Wednesday, February 16, 2005 - St. Clair arrived at the work site at 8:00 am. Weather was clear. Marin County Arborist crew was present at the site. St. Clair contacted Ford and left voicemail that crew was on-site and working. St. Clair stayed on-site to monitor. Crew concentrated on removal of Cypress Trees located near Battery Miller. Ford arrived at the site at 10:00 am. It was decided that it was unnecessary for URS staff to attend a 10:30 am weekly planning meeting taking place at Fort Baker. St. Clair returned to the URS Oakland office. At 3:45 pm St. Clair returned to the work site to check-up on the progress of the work crew. The crew was wrapping up the days work. Almost all of the Cypress Trees near Battery Miller had been cleared. Crew had a small bucket of materials recovered during the day. Materials included: modern glass beer bottles, a ferrous metal paint can, and possibly tin can. St. Clair transported the materials to the NPS/Presidio Trust Laboratory for review.

Thursday, February 17, 2005 - Ford contacted St. Clair around 1:30 pm. Ford informed St. Clair that the crew was going to fill the ruts created by machinery with hay. Ford asked St. Clair to inspect the areas where the ruts were created before it was covered. St. Clair arrived at the site at 3:45 pm. She inspected the ruts. No cultural materials were discovered in the area. She talked with the crew chief, who mentioned that a canister and some historical bottles were discovered earlier in the day and were taken to the NPS/Presidio Trust Archaeology Laboratory by Craig. St. Clair took a bucket of materials collected during the day. The materials mostly consisted of modern glass bottles. She transported the materials to the NPS/Presidio Trust Laboratory for review. She spoke with Hans (NPS) who showed her the collected materials that were transported to the laboratory earlier in the day. The bottles appeared to be some sort of historical food or medicine containers and were aqua in color. The metal container looked to be older and Hans was unsure of its function. Leo Barker will take a look at it and conduct additional research on the object.

Friday, February 18, 2005 - St. Clair arrived at the work site at 3:30 pm. Work crew had completed clearing areas around Battery Marcus Miller, Battery Boutelle and the low-lying area between the two batteries. Crew was laying out straw in areas that were becoming muddy and forming large ruts from movement of work equipment and automobiles in and out of the area. St. Clair left a message for George Ford that the crew had completed work in the area. She also contacted Vance Benté to notify him of the progress of the work crew. The work crew had a small collection of modern glass bottles and other modern debris at the site. St. Clair transported these materials to the NPS/Presidio Trust Laboratory for review. St. Clair was unable to get in touch with anyone regarding the Monday, February 21, 2005, President's Day Holiday. It is unclear if the crew will be working this day.

Monday, February 21, 2005 - Monday was President's Day. Crew was not working at the site. St. Clair did not visit the work area.

Tuesday, February 22, 2005 - Unfortunately, when St. Clair arrived to the site at approximately 4 pm, the work crew had already departed. St. Clair walked to "covered way" across from Battery Marcus Miller and Battery Boutelle. She observed a moderate amount of modern trash

on the ground surface. St. Clair contacted George Ford of the Presidio Trust and Leo Barker of NPS. She left voicemail messages indicating the work crew was not collecting all surface material and that she would return to the site in the AM the next day to remind the crew. Some of the trash observed included: food wrappers, glass soda and beer bottles, and aluminum soda and beer cans.

Wednesday, February 23, 2005 - St. Clair arrived at work site at approximately 8:00 am. Crew was working in the West Battery Area. They had cleared the area around Magazine 27 the day before. No cultural resources were collected from this area. Work crew informed St. Clair that they had not found any materials during brush clearing and tree removal on Tuesday. There was no bucket of material available to go the Archaeology Laboratory. St. Clair brought more buckets for collection of materials to the work site. She also left a voicemail message for George Ford and Leo Barker about her concern that the crew was not collecting materials. She was provided with contact information for Craig Benson of Schauff and Wheeler. Craig said that he would send David Thompson to monitor work crew's progress and collect any materials on the ground surface.

St. Clair returned to the work site at approximately 1:30 pm. David Thompson of Schauff and Wheeler, as well as two MacTech geologists, George Ford, and various NPS staff were present. David Thompson had collected as much of the ground surface material as possible. There was an abundance of material located on the west slope of Magazine 29 of the West Battery. Much of this material was not collected, but was noted. The materials not collected included: a dense scatter of glass wine bottles, glass beer bottles, aluminum beer bottles, food wrappers, several pairs of boxer shorts, condom wrappers, and various other sexual paraphernalia. Two large buckets of materials were collected and brought to the NPS/Presidio Trust Archaeology Laboratory for analysis by Leo Baker. This material included: glass soda and beer bottles, various metal parts (possible machinery), a plastic mug, and a canister of pepper spray.

Work crew informed St. Clair that they had completed work for the designated areas and would be returning in the coming weeks (once rain has ceased) to paint tree stumps and bushes with herbicide. It should also be noted that areas on the west upper slope of Magazine 29 and the west slope of Magazine 29 were not cleared because they contained plants native to the Presidio (sage and various other plants).

Monitoring of brush and tree removal has been completed. URS staff will return to the field for the next phase of work as planned.

Baker Beach Disturbed Areas

Cultural Resources Investigation

Brush/Tree Removal

Amendment to Daily Field Notes

- Tools used by the Marin County Arborists work crew during brush removal included the following: chainsaws, weed-whackers, large pick-up truck with trailer holding wood chipper, round and flat shovels, industrial sized dump trucks for collecting wood chips, small backhoe, and hand pushed mowers.
- Marin County Arborists also conducted Herbicide Application to tree stumps that were not completely removed.

- **2/14/2005 (Monday)** Began working in low-lying area (swale) between Magazine 21 and Magazine 22. Worked west towards cliff edge. Cleared low-lying brush, grasses and bushes.
- **2/15/2005 (Tuesday)** continued brush clearing in same area as mentioned above. Continued to clear low-lying brush, grasses, and bushes. Also began to remove trees from Magazine 21 area.
- **2/16/2005 (Wednesday)** Concentrated on removal of Cypress trees located on and around the slope of Magazine 21.
- **2/17/2005 (Thursday)** Continued with removal and splintering of trees on and around Magazine 21.
- **2/18/2005 (Friday)** Completed clearing low-lying brush, ivy, grasses, and bushes in the area between Magazine 21 and 22.
- **2/22/2005 (Tuesday)** Cleared low-lying grass, brush, and bushes on and around Magazine 27. This included the frontal slope facing west towards the parking lot and the "covered way" area on the east side of Magazine 27. Also began brush removal in low-lying area between Magazine 28 and 29.
- **2/23/2005 (Wednesday)** Cleared low-lying grass, brush, bushes and dense amount of poison oak located on and around Magazines 28 and 29. Also removed trees that were on top and around Magazines 28 and 29.

Baker Beach Disturbed Areas

Cultural Resources Investigation

Geotechnical Investigations

Daily Field Notes

Field Notes – Baker Beach Disturbed Areas (BBDAs) 1, 1A, 2 and

Tuesday, April 5, 2005 – A project kick-off meeting was held at 9:30 am. Andy Sheaffer, President and Brian McNeil, Superintendent of AIS Construction, Anne Henke, Project Geologist of Mactec, and Michelle St. Clair, Archaeologist of URS were present. Hans Bernal, Archaeologist of the NPS (NPS) was not able to attend due to prior commitments. Mactec is the prime contractor on the Baker Beach project and has devised schedule for the proposed field activities that was distributed March 30, 2005.

Henke conducted a walk through of all work areas of the project. She discussed issues regarding staging of equipment and the scope of work. Henke estimated that approximately two to three geological test pits will be dug per day. Mactec will be responsible for logging the test pits, photographing, and mapping. Issues regarding how to bring in equipment to access Area 1A of the project were discussed. Plan A is to bring the equipment over the frontal slope of Battery Miller. Plan B is to bring equipment under the Golden Gate Bridge along the frontal slope of Battery Cranston. AIS staff preferred Plan B for access. St. Clair voiced concern over the effect the machinery would have on the frontal slope of Battery Cranston and did not want to make a decision until Vance Benté, Project Manager of URS was consulted. Henke asked for clarification from URS on the involvement of NPS archaeologists on the project. St. Clair recommended that Mactec first contact URS and that URS will convey information to NPS archaeologists.

Wednesday, April 6, 2005 – Work began today at 8:00 am in Area 2 of the project. Two geological test pits were placed in this area. Two Shelby Tube Samples were taken at each location. Henke began the day with a safety meeting for all work crew.

BB2TP101 was the first test pit excavated. Work began on this pit at approximately 8:30 am. The pit revealed a 3-6” layer of topsoil over an approximately 12” layer of debris that is likely the result of U.S. Army dumping activities in this area. The debris included concrete, brick, tile, metal, and glass fragments, as well as some wire, and degraded metal parts. An intact glass cathode ray tube was recovered, as well as a “D-Patent” Coca Cola bottle that was in production from 1938 to 1951. Under the debris layer was an approximately 9’ layer of sandy silt soil with inclusions of serpentinite rock encountered towards the bottom 8’ to 9’. A serpentinite rock formation was encountered at 9’.

BB2TP100 was the second test pit excavated. It was located down slope (north) from BB2TP101 on a flat shelf. Work began on this pit at approximately 11:30 am. There was no observable debris layer in this pit. The pit contained approximately 10” of topsoil and an organic sandy silt soil that was dark brownish black in color. Mactec geologists were calling this layer of soil, “Colma.” Underlying this soil was 6’ of sterile native soil that was more of a sandy substrate, mottled, and orangish-brown in color. Serpentinite rock was encountered after this layer. No

historical materials were observed in this test pit. No hazardous materials were identified in the test pits.

(Vance Benté of URS visited the site to inspect the proposed access routes for equipment to Area 1A. Hans Bernal, NPS wanted to consult with Leo Barker, NPS before recommending how the work site should be accessed. Phone messages were left with Leo Barker, Steve Haller, and George Ford. Benté informed each of the decision to bring equipment under the Golden Gate Bridge and access the site via the frontal slope of Battery Cranston. It is believed that the thick layer of vegetation will provide a good buffer from possible impacts upon the topsoil layers of the frontal slope of the battery. The machine operator will be advised to move slowly and deliberately through the area making sure not to cause large ruts or impacts into the soil. The go-ahead to access the work area was received from Ford, Haller and Leo in the afternoon and early evening of April 6, 2005.)

Henke and Sheaffer met with the Golden Gate Bridge Authority at 1:30 pm to discuss access underneath the bridge. Equipment will be brought in between 7:00 and 8:00 am on Thursday to minimize impact on traffic.

Thursday, April 7, 2005 – Work began at 7:00 am. AIS had to walk equipment underneath the Golden Gate Bridge. Henke, St. Clair, and NPS biologists were on site to oversee the movement of equipment along the frontal slope of Battery Cranston. Rain caused conditions to be slightly muddy and damp. The movement of the spider excavator did cause compression of the grasses, plants, and brush in the area, but did not cause large ruts or pitting in the soil. Henke left the site for a doctor's appointment at 8:00 am. Bill Godwin of Mactec was present in Henke's absence.

Work on the test pit BB1ATP101 began at approximately 9:30 am. A small layer debris approximately 4" to 6" in thickness and consisting of roofing materials, was encountered at the uppermost layer. Underlying this material was a dark blackish brown layer of sandy silt with decomposing serpentinite at the bottom (approximately 5' in depth).

Test pit BB1ATP100 was dug north of BB1ATP101 at approximately 11:00 am. A single brick was recovered from the top layer of this pit. No other cultural materials were recovered in this test pit. It consisted of approximately 3' of dark blackish brown sandy silt, and changed to serpentinite rock at approximately 3' to 4'. Henke and Godwin of Mactec decided to extend test pit BB1ATP100 further to the north as a trench to see if any historical materials could be revealed in this area. No historical materials were recovered in the extended trench.

An exploratory trench (BB1ATP102) was also placed in the eastern slope of Area 1A to gain a better understanding of the extent of debris. The trench revealed that there was approximately 1' of topsoil over approximately 3' of roofing debris composed of black tar with sandy soil. No other cultural materials were observed mixed with this debris. Under the debris layer was native or sterile soil that was orangish brown in color and overlies a serpentinite rock formation.

One Shelby Tube (undisturbed sample) and three modified CA (disturbed samples) were taken from Area 1A for geotechnical testing. Under the direction of the Presidio Trust, Mactec also collected two environmental samples from BP1ATP101 for analysis of the PH. No hazardous materials were observed in the area. St. Clair stayed on site to oversee the removal of the equipment from the work area along the frontal slope of Battery Cranston. No additional disturbances were observed. Mactec plans no work for Friday, April 8, 2005, because the NPS

bird biologist must inspect Area 1 and Area 2 before work can proceed. The bird biologist is scheduled to visit the site Friday.

Friday, April 8, 2005 – Henke contacted St. Clair about work schedule for the following week. Because of rain, the bird biologist was unable to conduct his/her survey. The bird biologist will visit the site Monday to conduct survey. It is anticipated that geological work will start up at approximately 10 am after the bird biologist survey is complete.

Monday, April 11, 2005 – Arrived at work site at 10:00 am. NPS bird biologist and Daniel Edelstein, biologist with MACTEC were completing bird survey at this time. Spider excavator was being moved to site by AIS crew. At 10:30 am, Mactec, URS, and AIS personnel were briefed by biologists about birds present in the work area. An Allen's Hummingbird nest (special status species) was observed in a Lollipop tree in Area 1 where the proposed well is anticipated to be installed. The location of the nest is also near the proposed access route for BB1TP104. Mactec will work with Lewis Stringer of NPS to identify an alternate route to this proposed test pit and the significance of nest location to proposed upper seep well. A review of the health and safety guidelines for the project was conducted by Henke for the crew It took until 1:30 pm to utilize the spider excavator, drill and associated equipment into Area 1. The ground of the upper slope was extremely damp causing the spider excavator to move slowly through the area.

Work on test pit BB1TP100 began at approximately 1:45 pm. The test pit was excavated to approximately 7' in depth before encountering a layer of concrete rubble that impeded further investigation in this area. The topsoil of the test pit consisted of dark blackish brown sandy silt. Because of concrete rubble in the test pit excavations could not proceed. Therefore, native soils were not observed. Fill was observed throughout the 7' depth and included, corroded metal materials, nails, screws, a spark plug, and dense amounts of concrete rubble.

There was no indication of hazardous materials. Work concluded at 4 pm. The spider excavator was staged for work the next day.

Tuesday, April 12, 2005 – Work began at 7:00 am. The first test pit excavated was BB1TP105. The fill included extensive concrete rubble, brick with thick layers of mortar, corroded metal materials, slate roofing materials, black tar roofing materials, and a few glass bottles with twist tops that likely date to the 1930s/1940s. The fill layer in this unit extends over 11' in depth. Serpentinite bedrock was encountered between 10.5 and 12' in depth.

BB1TP101 was the second test pit dug. Fill in this area extended to over 17' in depth (which was the maximum reach of the excavator). The fill is primarily composed of concrete or cement rubble and also included one fragment of white porcelain that depicted an eagle with the words "United States Army" on it. Although serpentinite rock was not reached in this test pit, a mottling of the soils was seen towards the bottom 17' that displayed inclusions of serpentinite rock. A twist top soda bottle and medicine bottle (1930s/1940s?) were located east of BB1TP101 on the slope, as well as a melted piece of aqua glass, a fragment of WIE, and a large slab of orange colored marble.

BB1TP104 was dug mid-slope in a dense patch of poison oak. There was approximately 7' of fill present in this area. At approximately 7-8' a large Franciscan outcrop was encountered. Henke commented that the stratigraphy in this area displays intermittent periods of shale slough-off with layers of fill intermittent. She described it as being almost "alluvial" in appearance. The fill

in this area consisted of concrete rubble, tar, roofing materials, and various unidentifiable, corroded metal fragments. Because of the Franciscan outcrop encountered in the test pit, excavations did not proceed past 8'.

BB1TP103 was the final test pit excavated. Fill in this pit extended to approximately 9 ½' in depth. The fill in this pit contained "domestic refuse." The make-up of the fill included, twist-top glass medicine bottles, wine bottles, twist top liquor bottles, porcelain and WIE fragments, unidentifiable corroded metal fragments, asphalt-slate roofing material, and roof tiles. The materials in the fill appear to date to the 1930s/1940s time period. Serpentinite bedrock was encountered at approximately 10 ½' in depth.

There was no indication of hazardous materials. Two Shelby tubes were collected each from test pits BB1TP101, TP103, and –TP105 and one from BB1TP104 for geotechnical testing. Work concluded at 5 pm.

Wednesday, April 13, 2005 – Work began at 7:00 am. After set-up of equipment, work began at test pit BB1TP102. Work was stopped at 2 feet in this area because the spark plug had to be replaced on the spider excavator. The first two feet of BB1TP102 contained large amounts of "domestic debris" fill as was seen in BB1TP103. The test pit was temporarily backfilled to be revisited at a later date. At 9:00 am St. Clair left the site for a doctor's appointment. St. Clair returned to the site at 10:15 am. The spider excavator walked along the beach to access Area 2A of the project. Test pits BB2ATP103 and BB2ATP104 were excavated. Both test pits contained waste fill that consisted primarily of concrete rubble debris, slate roofing material, and amorphous metal fragments. BB2ATP103 was a shallow test pit that extended to 5' in depth. It contained very minimal amounts of waste fill; most notable was a large piece of metal wire. BB2ATP104 contained fill to a depth of 10-12' and was dug to 17' in depth (the extent of the spider excavator reach). The fill debris included concrete rubble, tile, slate roofing materials, and a couple of glass bottles.

Bottles discovered in BB2ATP104 include, a colorless glass Dr. Pepper bottle, a colorless glass Shield's Harper and Co. Motor Oil container, a indeterminate green glass wine or alcohol bottle, a colorless glass vinegar bottle, and a brown glass bottle that is likely a medicine bottle. All of the bottles appear to date to the 1930s/1940s time period.

No hazardous materials were discovered in this area. Two Shelby tubes each were collected from BB2ATP103 and BB2ATP104 for geotechnical testing. One environmental sample was collected from BB2ATP104.

St. Clair contacted Leo Barker, NPS Archaeologist in regards to test pits BB1TP103 and BB1TP102 that were showing large amounts of "domestic refuse" and how the NPS would like URS to proceed in light of the discovery. The domestic debris is mixed with construction debris and consists of WIE and porcelain vessels and fragments, broken and whole glass bottles and food containers, melted bottle glass, corroded metal materials, etc. Barker asked URS expressed to get a representative sample of materials from these areas. URS plans to collect a bucket-sized sample of materials from the area of test pit BB1TP102 when the spider excavator returns to Area 1.

Thursday, April 14, 2005 – Work began at 7:00 am. Armando Cuellar, archaeologist with URS will be joining St. Clair today to provide additional support during monitoring because of the

recent discovery of areas of domestic refuse. The spider excavator attempted to access the area of test pit BB2ATP100 in the early morning. Cuellar arrived on-site at 9:30am. He was briefed by Henke about the Health and Safety guidelines of the project. Cuellar was briefed by St. Clair about the project scope and archaeological aspect of the project. St. Clair and Cuellar met with Barker near Battery Boutelle at 10:00 am. Discussion involved a plan for sampling of domestic refuse in Area 1. Barker requested that URS take digital photographs of large construction type elements that are too large to collect, but are of interest. Barker planned to return to Area 2A later in the day to observe work activities taking place there. St. Clair contacted Vance Benté and Sean Dexter of URS in regards to the availability of a digital camera.

Due to the steepness of the slope, BB2ATP100 could not be accessed by the spider excavator and was installed at the BB2ATP101 location. BB2ATP101 was moved south of BB2ATP104 to evaluate the extent of waste fill in that area. BB2ATP100 (previously BB2ATP101) extended 5' before serpentinite bedrock was encountered. Fill in this area was shallow and consisted of wood (probably used in construction) broken glass, and slate roof tiles. Concrete rubble debris was not observed in large amounts.

BB2ATP101 contained waste fill to a depth of 12 to 14'. Large metal construction pieces and car parts were observed in the fill at this location. Metal parts observed included an I-beam, spring axel, and other various car parts. Other fill materials observed included slate roofing materials, wood, broken glass, and WIE and porcelain ceramic fragments. A distinctive layer of brick fill was located at approximately 7' in depth. Serpentinite bedrock was encountered at approximately 14' in depth.

St. Clair left the site to bring Leo Barker the representative materials from the domestic refuse areas of Area 1 for review. She also picked-up copies of maps and line drawings that were reviewed by Michael Lamb for his historical research on the use of the "tree island." St. Clair left a voice message for George Ford in regards to the work schedule for the tree island. St. Clair asked when URS should conduct research and an archaeological survey in the area. Mactec geologist, Bill Godwin, placed markers in the tree island to delineate trenching that will be taking place there. Godwin was unsure when trenching would take place in the tree island, but thought it may take place the week of April 18-22, 2005. Cuellar remained at the test pit location to monitor activities taking place there.

BB2ATP102 was placed in an area that was not originally depicted on the project map and was placed in lieu of the test pit area that could not be accessed by the spider excavator. Serpentinite bedrock in the this area was encountered at a depth of approximately 8'. Fill in the area contained, a concrete post or pillar possibly used to hold a fence line across the slope, melted glass, WIE and porcelain ceramics, various glass bottles, a thick piece of marble, wood posts, and possible wood siding. No slate roofing materials, brick, or tar was observed in this area. The fill extended to approximately 7' in this area.

No hazardous materials were discovered in this area. Two Shelby tubes were collected from each test pit. Work concluded at 5 pm.

Friday, April 15, 2005 – Work began at 7 am today. Armando Cuellar was present at the site to monitor geological testing activities. Test pits BB2ATP105 and BB2ATP106 (an additional test pit not depicted on the original map) were placed in Area 2A in the morning. Both test pit areas

were extremely shallow, and serpentinite bedrock was encountered between depths of 0.5' and 2.5' feet in both areas. A minimal amount of fill was observed in both test pits and did not contain domestic refuse. Most of the fill appeared to be construction debris that included wood siding, unidentifiable corroded metal, and possible roofing materials.

No hazardous materials were located in this area. One Shelby tube was collected from each test pit.

At 10:00 am Cuellar contacted St. Clair to notify her that the spider excavator would be moving from the Area 2A to Area 1 during low tied. St. Clair arrived at the site at 10:15 am to monitor work in the area of test pit BB1TP102 and to collect a representative sample of domestic refuse.

Area of BB1TP102 was extremely damp and difficult to access. It took over an hour for the spider excavator to reach the area of the test pit. The test pit was re-excavated. It contained domestic refuse mixed with construction debris. The fill extended to 17 feet (the extent of the spider excavator). Bedrock was not encountered. The fill consisted of broken and whole glass bottles, WIE and porcelain vessels, concrete rubble, and metal debris. Cuellar and St. Clair collected a bucket-sized sample to return to the Presidio archaeology laboratory.

No hazardous materials were observed in this area. Two Shelby tubes were collected from the test pits.

The spider excavator cleared back some of the area surrounding BB1TP102 to further get an idea about the extent of the domestic debris in the area. The material seemed to be concentrated near BB1TP102 in the general vicinity of the natural seep of the slope.

The work planned to take the rest of the day to stage the drill and associated equipment for the placement of the piezometers on Monday, April 18, 2005. Cuellar and St. Clair brought the collected materials from BB1TP102 to the Presidio archaeology laboratory for clean up at approximately 1 pm.

St. Clair and Cuellar met with Leo Barker who was concerned with the start-up of the cultural resources investigations for the Baker Beach project (to begin Wednesday, April 19, 2005). Barker was concerned that neither himself of Hans Barnaal would be able to monitor the activities in the area due to prior work and conference commitments. Barker contact George Ford to ask that the project be postponed until Monday, April 25, 2005.

After the meeting, St. Clair and Cuellar washed the representative artifacts from BB1TP102. St. Clair, Cuellar, and Barker spent approximately 45 minutes discussing the possible significance of the domestic refuse in the area. Barker asked that a discussion about this area that would involve Benté be scheduled for a later date.

Cuellar left the laboratory at 2:45 pm. St. Clair stayed to catalog the materials. (Please see *Catalog of Materials Recovered from Test Pit BB1TP102 from the Baker Beach Disturbed Areas 1, 1A, 2, and 2A project*.)

Monday, April 18, 2005 – Work began at 7 am. Cuellar was present at the site to monitor installation of piezometers in Area 1. Problems with the starter of the spider excavator delayed work. Cuellar left the site at approximately 1 pm.

George Ford sent out an email indicating that work on the cultural resource trenches would be postponed until Monday, April 25, 2005. Anna Henke contacted St. Clair to coordinate a meeting place and time to delineate the cultural resources trenches in the field. St. Clair and Henke decided to meet at 7 am on Tuesday, April 19, 2005.

St. Clair has not heard back from Ford in regards to the research and cultural resources survey for the "tree island" area of the project.

Tuesday, April 19, 2005 – St. Clair and Henke met at the work site at 7 am. White spray paint and nails with white flagging were used to delineate the proposed cultural resources trenches in the field. St. Clair contacted Barker and Barnaal by telephone, as well as sent a email to Barker, Barnaal, Henke, Ford, and Benté detailing the delineation in the field with a roughly drawn map. St. Clair asked that Barker and/or Barnaal visit the area in the next week to comment on the trench locations so that any necessary alterations or changes can be made before the beginning of work Monday, April 25, 2005. Ford responded to St. Clair's email commenting that the trenches do not need to extend into the magazine vents, and that careful exploration in the area should sufficient. St. Clair also commented that in consultation with NPS biologist, Lewis Stringer, the native plants flagged in the area of Magazine 27 will be carefully removed and replaced after the cultural resources trenches have been backfilled.

At 11 am Henke contacted St. Clair to notify her that in the area of piezometer BB1PZ100, an exploratory trench was placed to stage the drill (trench to be named by Henke post field investigations). Domestic refuse as was seen in the area of test pit BB1TP102 was discovered in this area. Henke will leave the area exposed so that St. Clair can investigate it when she returns to the field in the afternoon.

Monday, October 3, 2005 – St. Clair arrived at work site at 9:50 am. Others present included: Anna Henke, Geologist with MACTEC, Jim Nores, Project Superintendent with ERRG, and Enrique, laborer with ERRG. Purposes of these investigations were to investigate the extent of historic fill in the area of the parking lot strip and covered way north of Merchant Road and south of Baker Beach Test Area 1. According to historian John Martini's research of the of land use of the area by the military, there is the potential for debris and fill to be present in these areas.

Anna Henke began the day with a safety meeting and a review of how the test pitting investigations would proceed. Using a backhoe with a 24" tooth bucket, 3 test pit trenches were to be investigated. The plan is to remove approximately 4' of soil from a trench and then stop to the allow the geologist to further investigate by entering the trench. Further investigation will continue to a depth of 10' or however deep is required to reach native soil.

We began with the investigation of BB1TP107 located on the ridge of the covered way area and just north of Merchant Road. The area was covered in ivy and other types vegetative overgrowth. Excavations proceeded to a depth of 4' initially. Approximately 4 brick fragments and 6 fragments of concrete were observed in the uppermost 2' of the trench. BB1TP107 contained approximately 4 inches of dark brown organic top soil, overlaying approximately 2' of the colma derived fill observed in other areas of Baker Beach during previous investigations. Other refuse observed in the colma fill included a fragment of sewer pipe and various types of gravels. The trench was excavated to a length of 29' running east-west. At 4' Henke halted the excavation so

that she could enter the trench and take some samples of the soil. After Henke collected samples the excavations continued in the trench. At approximately 4' to 5' in depth a layer of large sized, water worn cobbles was encountered. These cobbles appeared to be roughly the size of a football and larger. They are not native to the area. The cobbles were loosely packed together and were consistent throughout this layer. Dark brown sandy silt soil appeared between the cobbles. This soil is similar to the soils observed near Magazines 27 and 28 during previous investigations. St. Clair notified Vance Benté, historical archaeologist with URS, as well as George Ford, Project Manager with the Presidio Trust of the cobbles. Ford noted that he has encountered these types of cobbles in various areas throughout the Presidio, and although they are not native, they were used in construction projects such as walls. The current cobble layer encountered at BB1TP107 does not appear to be a specific structure. These cobbles may have been dumped in this area as part of a fill episode. Some of the cobbles were pulled aside for review by George Ford. Excavation in the trench proceeded to approximately 13' in depth. Beneath the cobble layer was more colma fill that transitioned to serpentinite derived soils and then serpentinite bedrock starting at approximately 8' in depth.

At 1:15 pm MACTEC geologist Bill Godwin and George Ford of the Presidio Trust arrived at the work site. There was some discussion about the placement of BB1TP109 and its proximity to the Golden Gate Bridge Transportation Authority modulars and existing utility lines in the area. It was decided that the trench would be placed along the hillside of the covered way.

BB1TP109 excavations began at 2:49 pm. Fill was encountered in this trench including older rebar, concrete and brick debris, a rubber bumper, a metal pop top pull, and a green glass bottle with a crown cap. The green bottle appears to be a Mickey's Malt Liquor bottle with a crown cap. The bottle had the following embossed on it: [PLEASE DON'T LITTER/ PAT. PEND./ 534 NW 80]. Roofing tar and a red chert layer were encountered at approximately 2' below the surface. Henke took samples of the fill layer and the native colma soil. At approximately 7' in depth the native colma layer was reached and excavation in this area ceased.

Work ended at 5:00 pm.

Tuesday, October 4, 2005 – Arrived at work site at 7:30 am. The Golden Gate Bridge Transit Authority had to clear two abandoned automobiles from the site area so that work could proceed in the area. Jim Nores of ERRG arrived at the work site at 8:00 am. Work began on excavation of BB1TP108 that ran north-south and was located immediately north of Merchant Road. BB1TP108 contained a 1' to 1.5' layer of modern roadbed made up of light grey soils and gravel. At approximately 2' a red chert layer was encountered. Above the chert layer was a layer of disturbed colma fill that contained some small brick fragments and concrete fragments. An older sewer pipe that was no longer working was discovered in the side wall of the trench at approximately 1' below ground surface. Beneath the red chert layer was what Henke called, "colma derived fill" that contained fragments of brick and concrete. At approximately 7' to 7.5' feet, native colma was encountered. Henke took samples of the fill above and below the chert, as well as the native colma soil in the trench. In total, this trench was approximately 12' in length and began approximately 8' from the white edge stripe that is painted along Merchant Road. It was decided not to extend the BB1TP108 trench the entire length of the test area, and rather to get a sampling of the soils further north to trace the extent of the fill in the area.

George Ford arrived at the site and recommended that Henke return to the BB1TP107 trench site to sample the layer of fill soil that occurred above the cobble layer encountered. The backhoe excavated a trench immediately adjacent to the filled-in BB1TP107 trench. This trench was similar in stratigraphic layers to BB1TP107, except that the fill layer contained a much heavier concentration of fragmented bricks, including fragmented bricks with mortar. The bricks contained a large aggregate that was yellow in color. Henke took a sample in this trench of the fill layer above the cobbles and noted that the fill appeared to be colma derived.

BB1TP108 (Auxiliary) was excavated further north of the original BB1TP108 to trace the extent of the red chert layer and fill layer. Fill extended to approximately 7', where the chert layer was encountered (7') and appeared to be mixed with asphalt. The fill contained brick, concrete, and amorphous metal fragments. Below the chert fill, a type of topsoil development was encountered with oxidized fragments similar to what was seen in trenches during the cultural resources investigations. There is also what appears to be a layer within the 7' of fill that is a windblown sand layer that may be representative of an area remaining open for a period of time, allowing for a thin sand accumulation before being filled. This trench was stopped before reaching the native colma layer, as the purpose of the trench was to investigate the extent of the fill in these areas. The auxiliary trench for BB1TP108 extended approximately 10' in length. Overall, it indicates that the present ground surface is built up 2' to 7' above the episodes of fill and chert in this area. It indicates that the historical ground surface may have trended downwards as it extended to the north towards the covered way.

Baker Beach Disturbed Areas

Cultural Resources Investigation

Specific Cultural Resources Investigations

Daily Field Notes

(*Notes from Michelle St. Clair 4/25/05 – 5/6/05*)

Monday, April 25, 2005 - Work began at 7:00 am. This phase of work included the installation of Cultural Resources trenches. Work began with a safety meeting and overview of project objectives. People present at the work site included: Anna Henke (MACTEC), Vance Benté (URS), Christopher Lee (URS), Michelle St. Clair (URS), George Ford (Presidio Trust), Leo Barker (NPS), Hans Barnall (NPS), Lewis Stringer (NPS), and backhoe operation crew from ERRG. Began by excavating Trench 3. Backhoe operator was instructed to excavate approximately eight inches at a time. Backhoe began work with a 2 ½' wide, three comb bucket.

Fill in the Trench 3 did not match the anticipated pattern for the area. The parking lot ground surface was underlay by a layer of dark sand at approximately 12 to 13" below ground surface and approximately 12 to 14" thick. The loosely compacted sand overlay what was deemed the mottled "colma/fill" layer in the field. This layer was approximately 4 ½' thick. Under this layer was a relatively level layer of what appears to be dark blackish brown soil that contained some organic materials and rootlets. It was suggested this dark layer may represent the sodding layer of the West Battery. The dark blackish brown soil layer was first encountered at approximately 5 ½ ' below ground surface. It appears to be about 2' in thickness. It was decided to excavate Trench 3 to the extant of the backhoe arm. At 7 ½' a compressed pinecone was recovered. Under the dark blackish brown layer was a transition to the native soils (called "colma" in the field) Colma is made up of clay with serpentinite formations. The trench advanced to 13 feet below ground surface. St. Clair drew a sidewall profile of Trench 3 entitled, *Trench 3 – Initial Excavations 4/25/05*. No cultural materials, besides the pinecone, were discovered during excavation of the trench. Barker suggests that the frontal slope may need to be tested further north of Trench 3, directly in front of the battery wall. This will help to further investigate the theory that the dark brown soil layer represents sod or topsoil that was placed a top the battery or magazine and later moved.

An additional short trench (deemed Trench A in the field by Henke) was placed perpendicular to Battery Godfrey to trace the extent of the dark blackish brown soil layer. Under the modern parking lot ground surface was a layer of approximately 6" of red chert gravel. This layer may be an older roadbed. Under this level was a layer of mottled "Colma" fill mixed with multiple lifts of dark brown sandy silt. The level was approximately 3 ½' thickness. It changed to what appeared to be strictly colma/fill that was approximately 2' in thickness. At approximately 6' below ground surface, there was a change to what was previously described as the dark blackish brown soil layer. This was approximately 3' in thickness. After lunch, Trench A was extended west to trace the extant of the dark blackish brown soil layer. It was theorized that the dark brown soil layer represented something nonnative to the area and was introduced. No cultural materials were observed while excavating this trench. St. Clair drew a sidewall profile of Trench A entitled, *Trench A 4/25/05*.

An additional short trench (deemed Trench B in the field by Henke), was placed further north of Trench A. It was also perpendicular to Battery Godfrey. Initial excavations next to the Battery wall revealed that the modern parking lot surface was underlain with approximately 6" of red chert gravel. Under this level a layer of sand was encountered. One machine made, amber glass bottle with twist top was recovered from the sand level. It was not understood if the sand represents original sand dunes in the area or if it was used as fill material. It was decided that Trench B would be further extended west into the parking lot the next day. Work ended at 3:30 pm.

Tuesday, April 26, 2005 - Work began at 7:00 am. Trench B was extended to the west to trace the sand level. Sand level was discovered to interface with the colma/fill level at approximately 22' from the wall of Battery Godfrey. Trench B was extended to a depth of 9' and was a total 33'. A plastic bag was recovered from the first 1' of the sand layer of the trench. No other cultural materials were observed. St. Clair drew a sidewall profile of Trench B entitled, *Trench B 4/26/05*.

Per direction of the URS staff, it was decided to extend Trench 3 approximately 100 feet north of the original trench location. The modern parking lot surface was underlay by approximately 6" of red chert gravel. Under the red chert layer was a layer of colma/fill approximately 5 to 5 ½' thick. This fill layer contained some brick debris. Representative samples of brick were collected for examination in the NPS laboratory. At approximately 6' the dark blackish brown soil layer was encountered. This level was approximately 2' in thickness. Rootlets were visible in the soil. A sample of this soil was collected for further investigation of the types of roots or seeds present. At approximately 8 to 9' throughout Trench B, native bedrock (colma with serpentinite rock inclusions) was encountered. No other cultural materials were encountered. St. Clair drew a sidewall profile of Trench 3 entitled, *Trench 3 4/26/05*.

The backhoe bucket was changed to a "flat" bucket before beginning work on Trench C to protect the walls of Battery Godfrey. It was discovered that the battery wall was actually an approximately 2' thick concrete apron. The apron of the battery was over- and underlay with dark brown sandy silt soil. At the bottom of the slope of the battery, the topsoil changed to the modern day road gravel underlay by approximately 6" of the red chert gravel. Approximately 5 to 5 ½' of colma/fill underlay this layer. Dark blackish brown soil was encountered at approximately 6 to 6 ½' and was approximately 2' in thickness. Native soil or bedrock was encountered at approximately 9' and contained serpentinite rock formations. No cultural materials were observed. St. Clair drew a sidewall profile of Trench C entitled, *Trench C 4/26/05*. Work ended at 3:30pm.

Wednesday, April 27, 2005 - Work began at 7:00am. Trench 1 was excavated from the vent of Magazine 27 to the vent of Magazine 28. Trench work began at the vent of Magazine 27. A "flat" bucket was used to protect the magazine walls. A thin layer of topsoil (less than 6" in thickness) overlays the magazine structure and extends down the slop of the magazine until it stops at the parking lot surface. Under the topsoil, and directly against the magazine structure was a compact layer of grayish black clayey soil. This layer was approximately 6 to 8" thick. Against the magazine there was evidence of an excavated trench (possibly for construction of the magazine) that was 20" wide and extends into the native "Colma" soil of the area. At the bottom of this trench at approximately 13 to 14' below ground surface, a layer of bricks 2 courses high

and 2 to 3 courses wide was discovered. The bricks were directly abutted against the magazine wall. A layer of colma/fill appeared to have been laid on top of the clay layer that was placed directly against the magazine. In the south end of the trench that extends out from Magazine 27 there was evidence of the red chert gravel. It occurs at approximately 1' below ground surface, approximately 8' south of the magazine wall, and continues to run south. The native colma layer was encountered at approximately 14' below ground surface. No cultural materials were discovered during the excavation of this side of the trench. St. Clair drew two sidewall profiles of Trench 1 entitled, *Trench 1 – Magazine 27 4/27/05*.

Trench 1 was extended southward towards Magazine 28. The statigraphy was similar to that described above. There was evidenced that the colma/layer was trending downwards (deeper) as the trench moved southward. The coma/fill layer appeared to be intermixed with dark brown tidal sand towards the south end of the trench. A thick layer of red chert gravel overlay the colma/fill layer. The red chert gravel layer was thicker than observed in any other area investigated. The red chert gravel was approximately 1 to 1 ½' in thickness at this location.

Under the direction of MACTEC, Trench 3 was continued south toward the intersection with Trench 2. It was dug to a depth of 4' to investigate the possibility of refuse. Statigraphy in the trench was similar to what was observed at the more northern ends of Trench 3. Under the modern surface of the parking lot was a 6" thick layer of red chert gravel. The colma/fill layer underlay this level. It was approximately 2 ½' thick and trended downward toward the southern end of the trench. The fill layer in the end of the trench contained wire, glass, nails, corroded metal and wood debris towards the far southern end. A coke bottle, wire nail, amber glass fragment, and Nee-Hi bottle were recovered. Materials were collected for analysis at the NPS laboratory. St. Clair drew two sidewall profiles of Trench 3 entitled, *Trench 3 – Southern End 4/27/05 and Trench 3 4/27/05*. Work ended at 3:30 pm.

Thursday, April 28, 2005 - Work began at 7:00 am. Began by excavating the section of Trench 1 against Magazine 28. Statigraphy on this end of the trench appears to be similar to that of Magazine 27. A 10" layer of dark blackish brown soil (compact and somewhat clayey) was placed directly against the magazine walls. There was evidence of an excavated construction trench approximately 20" wide abutted against the magazine structure. No brick platform was observed in the bottom of the trench. The dark blackish brown soil appeared to have been dug into and overlays the native "colma" soils that contained serpentinite inclusions. Over the dark blackish brown soil was the colma/fill layer. Over this there was a topsoil layer that was organic and contained an abundance of poison oak. The topsoil layer was approximately 3" in thickness. No cultural materials were observed. St. Clair and Barnaal drew a sidewall profile of the south end of Trench 1 entitled, *Trench 1 – Southern End of Magazine 28 4/28/05*.

Trench 2 was excavated to a depth of 14' throughout. A large refuse deposit that contained mostly 1930s era historic materials was encountered in the west end of the trench. The trash deposit included, cyclone fencing, bay and eucalyptus tree cuttings, broken brick pieces, Acme aluminum beer can, Pabst Blue Ribbon aluminum beer can, clear glass bottle neck, amber glass beer bottle, men's leather shoe sole, saw cut cow rib, coca cola bottle, Regal Pale Ale beer bottle, Brown Derby Pilsner Beer can, roofing paper, Green Glenn Dairy glass bottle (from San Francisco), and various other broken bottles and ferrous metal pieces. All materials were collected for analysis at the NPS laboratory. The colma/fill layer, blackish brown soil layer, and

the native colma all trend abruptly downward in the west end of the trench. St. Clair drew a sidewall profile of Trench 2 entitled, *Trench 2 – West End 4/28/05*. Work ended at 3:30 pm.

Friday, April 29, 2005 - Began day at 7:00 am. Trench 1 was extended north from Magazine 28 to trace the extant and depth of an apparent cement washout in the area. After probing with the backhoe bucket it appeared that the cement was more than 3' in depth. A decision was made to cease excavation of this trench.

Trench 2 was extended east toward the intersection with Trench 1. Trench 2 was excavated to 95' total in length. The red chert gravel layer was approximately 1 ½ to 2' in thickness at the eastern end of the trench. Underlying the chert at the east end was dark brown tidal sand with some inclusions of colma/fill toward the top of the layer. The sand layer was approximately 3 ½' to 4' in thickness and transitioned to completely sand with no colma inclusions at approximately 5 feet in depth. No cultural materials were observed. St. Clair drew a sidewall profile of Trench 2 entitled, *Trench 2 – East End Past Trench 4/29/05*.

Per the direction of URS staff an additional trench was placed extending off of Magazine 28 west toward Trench 2 (deemed Trench D in the field by Henke). A dark blackish brown layer of soil was abutted against the magazine wall. Over this was a layer of colma/fill. The topsoil was approximately 3-6" thick. Beneath the blackish brown soil, native colma with serpentinite rock inclusions was encountered. No cultural materials were recovered from this area. St. Clair drew a sidewall profile of Trench D entitled, *Trench D – Southeast End 4/29/05*.

The backhoe blew a hydraulic house at 10:15 am. Work was stopped and Benté and St. Clair returned to the URS Oakland office.

Monday, May 2, 2005 - Work began on the area adjacent to Marcus Miller and Battery Boutelle. ERRG crew set-up safety fencing. Barnaal mapped out locations of the original mortar barbettes. Excavation work on the trenches began at approximately 10:15 am. Trench 4 was excavated to approximately 11' in depth. Complex statigraphy was encountered. Approximately 2' of topsoil overlay approximately 2' of red chert gravel. In the east side of the trench evidence of a black tar roadbed underlay the red chert gravel. Under the red chert gravel was a layer of sand dug for a gas line that was encountered, blackish brown soil, and clayey type of colma. A consistent and level layer of sand was encountered at approximately 6' in depth below the ground surface. Native colma soils underlay all of the aforementioned layers and changed to serpentinite bedrock formations at the bottom. No cultural materials were observed. St. Clair drew a sidewall profile of Trench 4 entitled, *Trench 4 5/2/05*.

Per the direction of URS staff a trench was placed north of Trench 4 (deemed Trench E in the field). Trench E was dug to a depth of approximately 6 ½'. The trench was extended approximately 65' west. The gas line was also encountered in this trench. Some concrete rubble was encountered in the eastern end of the trench next to the slope of the covered way. This rubble may have been used to brace or support the slope of the covered way. At approximately 35', and extending to 57' (22' in length total), a large cement pad was encountered in the trench. The trench was 8" in thickness and was encountered at a depth of 4'. The cement pad appeared to be placed at the same level as the red chert gravel at the eastern edge of the trench. The cement slab corresponds with the current plotted location of the incinerator. The statigraphy of the trench was as follows: approximately 3' of top soil, with 6" of red chert (or the cement pad)

underlying this, 2' of blackish brown sandy silt soil, turning into colma/fill/clay below. Some historic materials dating to the 1930s were recovered. The materials were collected and taken to the NPS laboratory for processing. Excavations were halted at the cement pad so that Benté and Barker could investigate the next day. The trench was left open. Barnaal and St. Clair shot elevation points of features and levels of the open trenches. Work ended at 3:30 pm.

Tuesday, May 3, 2005 - Work began at 7:00 am. Barker and Benté visited the two trenches opened on Monday. St. Clair drew a sidewall profile of Trench E entitled, *Trench E 5/3/05*. Work at Trench 6 involved peeling back soils that had filled in the entrance to the magazine, so that staff could enter the magazine. Granite steps that enter into the magazine were encountered and crew had to move to hand excavation of the trench to prevent damage. The soils that filled in the magazine contained modern and historic refuse that was collected. Materials collected were taken to the NPS laboratory for examination. Elevation points were of the magazine entrance were taken by Barnaal. Work ended at 3:30 pm.

Wednesday, May 4, 2005 - Work began at 7:00 am. Trench 5 was excavated south of the magazine. The trench was approximately 42' in length and excavated to approximately 12' in depth. Statigraphy was similar to that seen at Magazines 27 and 28. A layer of dark blackish brown sandy silt was placed against the magazine structure. This soil contained more sand and less clay than at Magazines 27 and 28. The excavated construction trench was not a clearly delineated in this trench as it was in the others. Approximately 1 to 1 ½' of topsoil overlay the entire trench. Beneath this layer was a layer of fill/colma that was approximately 4 to 4 ½' in thickness. A sandy fill layer, underlay by the red chert gravel road was abutted against the dark blackish brown sandy silt at approximately 5 ½ to 6' in depth. In the bottom of the dark blackish brown sandy silt, a layer of sand and mixed brick was encountered. Samples of the bricks, including bricks with mortar, were collected and taken to the NPS laboratory. It was theorized that the brick represents spoils from the construction of the magazine. Trench 5 was extended to Trench E. No sign of the cement pad was found in Trench 5. Trench 5 was continued past Trench E to trace the extent of the cement pad. Refuse, ash, and burned material was encountered in the south edge of the trench adjacent to the cement slab. Some of these materials were collected and taken to the NPS laboratory for analysis. Work ended at 3:30 pm.

Thursday, May 4, 2005 - Work began at 7:00 am. St. Clair began day by drawing sidewall profile of Trench 5 entitled, *Trench 5 5/5/2005*. Trench 4 was exposed to the north and south to investigate the "sand layer" and to look for possible evidence of postholes associated with the mortar barbette. At the interface of the dark blackish brown soil layer and the sand layer, thin layers of redwood (appearing to be planks) were encountered. Trenching was stopped and URS crew worked with hand tools to peel back the layers of soil and reveal the wood. It was theorized that the wood represents the remnants of the mortar barbettes and matches with elevations recorded on historical maps for the area. Extensive digital photographs were taken by Barnaal and Barker of NPS and elevation points were recorded by Barnaal. Work ended at 3:30 pm.

Friday, May 6, 2005 - Work began at 7:00 am. The backhoe blew a hose early in the morning and work in the area was delayed. Benté and St. Clair investigated the profile of Trench 5 while waiting for the hose to be fixed. Once the hose was fixed, the crew began to extend Trench 4 to the south to investigate the size of the mortar barbette. The gas pipe previously located in the trench was broken. Work was stopped until PG & E can investigate.

Backhoe moved to the Merchant Road Tree Island area to dig three geological test pits. St. Clair was present to monitor for cultural resources. Test Pit "C" was dug to 5' in depth. The trench was 2' of organic topsoil underlay by the native colma formation to 5'. There was no evidence of imported fill in the area. Test Pit "B" was dug to 5' in depth. The trench was 2' of organic topsoil underlay by native colma formation to 5'. Test Pit "A" contained a layer of red chert gravel at 2' below ground surface, underneath the organic topsoil. The red chert was visible in other areas of the Merchant Road Tree Island and may indicate an earlier road alignment in the area.

Work concludes at 2:30 pm and it was decided that URS will return to the field for 2 additional days to complete the cultural resources investigation of Trench 4 and the associated mortar barbette area.

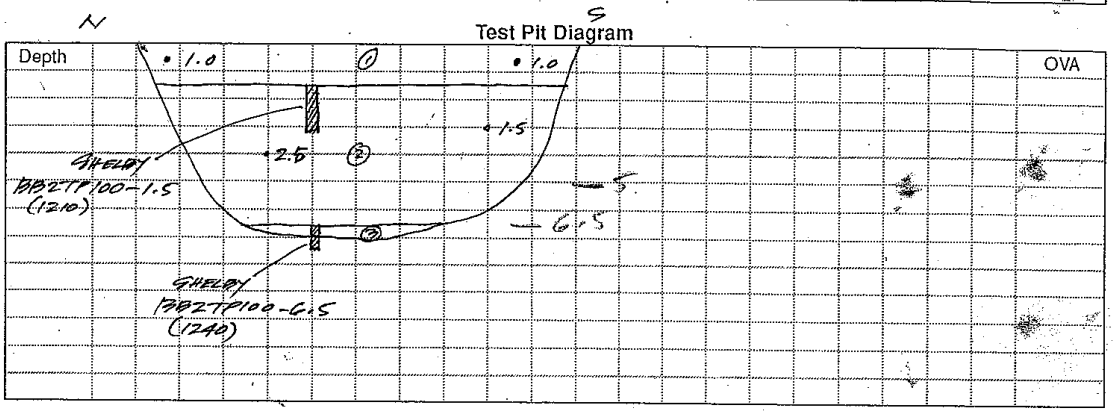
Test Pit Diagram



Test Pit Descriptions

Description:

① VERY DARK GREYISH BROWN CLAYEY GRAVEL (GC) (10YR 3/2) LOOSE. MOIST TO WET. 60% GRAVEL (ANGULAR) 30% CLAY/FINES 10% SAND. REFUSE IN LAYERS MINOR AMOUNTS OF GLASS SHARDS THROUGHOUT.

② DARK GREYISH BROWN SANDY LEAN CLAY (CL) (10YR 4/2) SOFT. MOIST. 70% CLAY/FINES 30% SAND. LITTLE TO NO REFUSE

(2A) COLOUR & MOISTURE CHANGE OLIVE GREY (5Y 4/2) WET.

③ VERY DARK GREYISH BROWN WELL-GRADED GRAVEL (GW) (10YR 3/2) LOOSE. WET. 70% GRAVEL (ANGULAR SILTSTONE) / COBBLES (SERPENTINITE) / CONCRETE CHUNKS.

④ MELANGE WITH SERPENTINITE. DARK OLIVE GREY

Sample Numbers: MELANGE (K) (5Y 3/2) WET. MODERATELY CONSOLIDATED INTENSELY FRACTURED. LOW HARDNESS. FRIABLE TO WEAK.

Additional Information: DEEPLY WEATHERED.

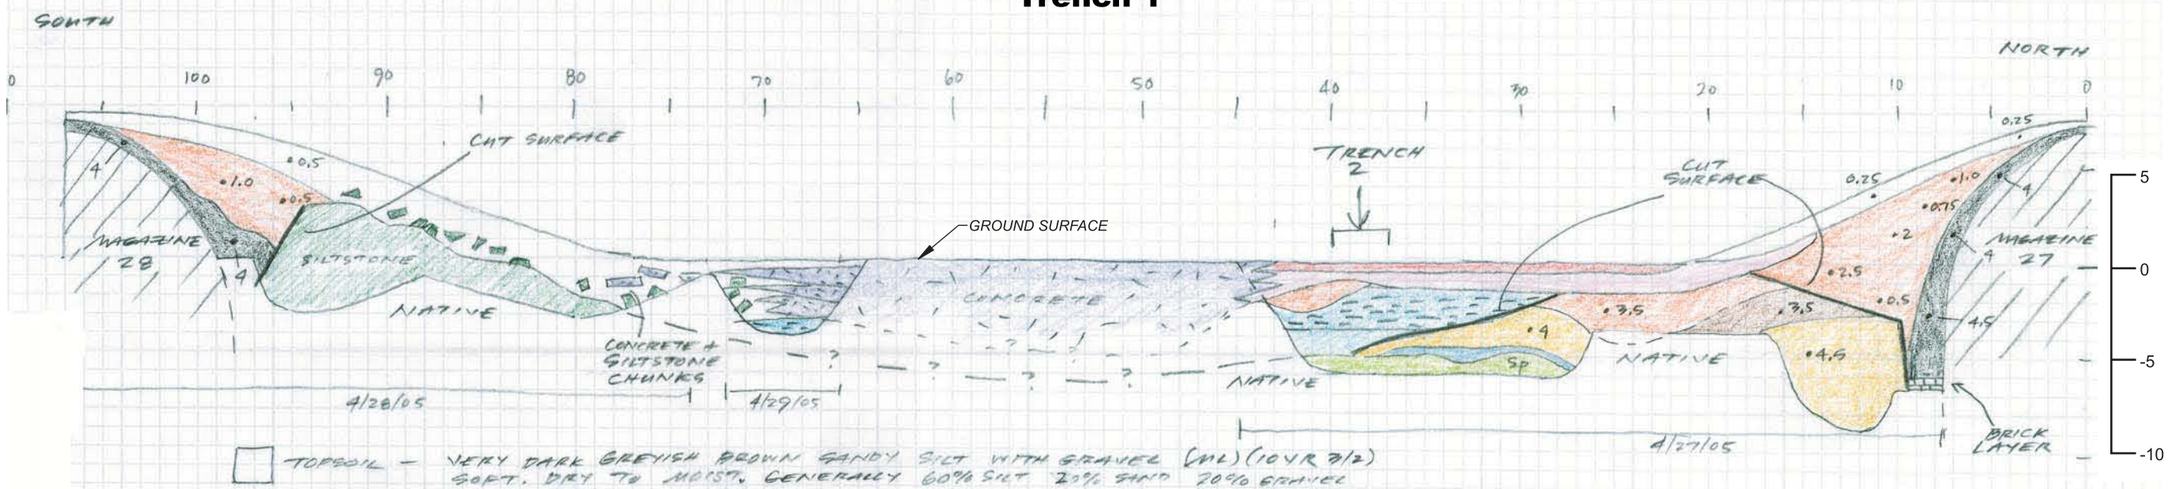
Appendix D
Soil Profile Overlays

Trench 1



TOPSOIL – VERY DARK GREYISH BROWN SANDY SILT WITH GRAVEL (ML)(10YR 3/2) SOFT. DRY TO MOIST. GENERALLY 60% SILT 20% SAND 20% GRAVEL

MIXED CLAY FILL – MIXTURE OF YELLOWISH BROWN (10YR 5/6) AND VERY DARK BROWN (10YR 2/2) LEAN CLAY (CL) SOFT. MOIST., 80% CLAY 20% SILT. OCCASIONALLY SANDY.

CONSTRUCTION CLAY – BLACK LEAN CLAY (CL) (10YR 2/1) HARD TO VERY HARD. MOIST. 100% CLAY. COMPACTED ON SIDES OF STRUCTURES.

CONCRETE – MULTIPLE LAYERS OF CONCRETE AND CEMENT GROUT (SOME WITH COLOURING AGENTS ADDED) PRESUMED TO BE AN OLD WASH OUT AREA.

CHERT FILL (1) – DARK REDDISH BROWN WELL-GRADED GRAVEL WITH SAND (GW)(5Y 3/3) DENSE. DRY. 70% GRAVEL (ANGULAR CHERT TO 1.5" Ø) 20% SAND <10% FINES.

CHERT FILL (2) – AS ABOVE, BUT LIGHTER COLOUR - REDDISH GREY (5Y 5/2)

FILL SAND (1) – VERY DARK GREY POORLY GRADED SAND WITH CLAY INCLUSIONS (SP)(5Y 3/1) LOOSE TO MEDIUM DENSE. DRY TO MOIST. 70% SAND. 30% YELLOWISH BROWN CLAY.

FILL SAND (2) – VERY DARK GREY POORLY GRADED SAND (SP)(5Y 3/1) LOOSE TO MEDIUM DENSE. MOIST. 100% SAND.

NATIVE MATERIALS

SILTSTONE – OLIVE GREY SILTSTONE (5Y 5/2) ( ) MODERATELY CONSOLIDATED. CLOSELY FRACTURED LOW HARDNESS. WEAK. DEEPLY WEATHERED

CLAY (1) – VERY DARK GREYISH BROWN LEAN CLAY (CL) (10YR 3/2) HARD. MOIST. 80% CLAY 15% SILT 5% VERY FINE GRAINED SAND.

CLAY (2) – YELLOWISH BROWN LEAN CLAY (CL) (10YR 5/6) HARD. MOIST., 100% CLAY. WITH FeO_2 MOTTLE, AND BLACK OXIDATION ALONG FRACTURES. IN PLACES RESEMBLES WEATHERED ROCK.

SAND – DARK GREYISH BROWN SILTY SAND (SM) (2.5Y 4/2) DENSE. WET. 60% VERY FINE SAND 40% SILT/FINES. HAS BEDDING PLANES. THIN LAMINATIONS.

SERPENTINITE – LIGHT OLIVE BROWN (2.5Y 5/3) TO GREENISH GREY (5BG 5/1). MODERATELY CONSOLIDATED. INTENSELY FRACTURED. LOW TO MODERATE HARDNESS. FRIABLE TO WEAK. DEEPLY WEATHERED.

Summary of Artifacts Recovered During all Investigative Activities for Baker Beach Disturbed Areas 1, 1A, 2, and 2A

Summary of Artifacts Recovered During all Investigative Activities for Baker Beach Disturbed Areas 1, 1A, 2 and 2A

Location	Area of Investigation	Collection Date	Description	Count
Presidio	Baker Beach 1, east side mound of brick powder magazine	nd (April 2005	clear glass medicine bottle, complete save for a top, across top front it says "QUALITY" and across bottom front it says "PURITY"; along back sides it gives measurements and says "3 VL" on top	1
Presidio	Baker Beach 1, east side mound of brick powder magazine	nd (April 2005	rusted iron hand crank/wrench	1
Presidio	Baker Beach 1, North slope of cement battery (Boutelle)	nd (April 2005	clear glass bottle, prob. liquor, flask-shaped, no label remains	1
Presidio	Baker Beach 1, North slope of cement battery (Boutelle)	nd (April 2005	metal cylinder, poss. aluminum, poss. a thermos, the mouth narrows towards the body of the thermos and the metal is folded over at the top, barely crushed; introduced circa 1913; reference: Aladdin-Stanley (800-251-4535)	1
Presidio	BBDA Trench 1, against Magazine 27	38469	Bricks, ranging in size from nearly complete specimens to fragments	11
Presidio	BBDA Trench 1, against Magazine 27	38469	ferrous metal: one nail, one long flat piece	2
Presidio	BBDA 1	38483	gas or recoil cylinder from semiautomatic rifle	1
Presidio	BBDA Trench 1, against Magazine 28	38469	Soil sample- sod pack against magazine structure 28	1 bag
Presidio	BBDA Trench 1, South end/ cement washout	38471	cement fragment	1
Presidio	BBDA; 1, 1A, 2, and 2A; Trench Area 1; Test Pit BBITP102 (representative collection) for URS	38457	black glass	1
Presidio	BBDA; 1, 1A, 2, and 2A; Trench Area 1; Test Pit BBITP102 (representative collection) for URS	38457	ceramic base fragment, showing floral design in red, green, blue, and black on cream; possible plate	1
Presidio	BBDA; 1, 1A, 2, and 2A; Trench Area 1; Test Pit BBITP102 (representative collection) for URS	38457	ceramic base fragment, showing poss. windmill design in blue, black, and red on white	1

Summary of Artifacts Recovered During all Investigative Activities for Baker Beach Disturbed Areas 1, 1A, 2 and 2A

Location	Area of Investigation	Collection Date	Description	Count
Presidio	BBDA; 1, 1A, 2, and 2A; Trench Area 1; Test Pit BBITP102 (representative collection) for URS	38457	ceramic rim fragment, whiteware with blue glaze on exterior and interior; poss. mug	1
Presidio	BBDA; 1, 1A, 2, and 2A; Trench Area 1; Test Pit BBITP102 (representative collection) for URS	38457	ceramic plate base fragment, white glaze with thick black stripe around circum. of plate and a thinner red stripe below it	1
Presidio	BBDA; 1, 1A, 2, and 2A; Trench Area 1; Test Pit BBITP102 (representative collection) for URS	38457	ceramic base fragment, lt. blue glaze, poss. plate	1
Presidio	BBDA; 1, 1A, 2, and 2A; Trench Area 1; Test Pit BBITP102 (representative collection) for URS	38457	ceramic rim fragment, whiteware with turquoise-blue glaze on exterior and interior; vase or large bowl; wheel made; cracks in glaze; copper-colored flecks on interior as well as some rust	1
Presidio	BBDA; 1, 1A, 2, and 2A; Trench Area 1; Test Pit BBITP102 (representative collection) for URS	38457	green wine bottle, complete, with small push-up base and “BOTTLE MADE IN ITALY” embossed around edge of base	1
Presidio	BBDA; 1, 1A, 2, and 2A; Trench Area 1; Test Pit BBITP102 (representative collection) for URS	38457	white glass bottle base; embossed in circle in center of base: “CORNING” (around top); “T.M. REG.” (in center, with a small human figure between them); and “MADE IN U.S.A.” along bottom	1
Presidio	BBDA; 1, 1A, 2, and 2A; Trench Area 1; Test Pit BBITP102 (representative collection) for URS	38457	ceramic rim fragment; poss. mug or bowl, white glaze, with a thick dark green stripe around exterior top and a thinner green stripe below it	1
Presidio	BBDA; 1, 1A, 2, and 2A; Trench Area 1; Test Pit BBITP102 (representative collection) for URS	38457	ceramic base fragment; poss. mug or bowl, white	1

Summary of Artifacts Recovered During all Investigative Activities for Baker Beach Disturbed Areas 1, 1A, 2 and 2A

Location	Area of Investigation	Collection Date	Description	Count
Presidio	BBDA; 1, 1A, 2, and 2A; Trench Area 1; Test Pit BBITP102 (representative collection) for URS	38457	ceramic utility pipe fragments, GE brand, with screws/metal attachments, one piece has "BRYANT" embossed on underside; rusty	4
Presidio	BBDA; 1, 1A, 2, and 2A; Trench Area 1; Test Pit BBITP102 (representative collection) for URS	38457	metal cylindrical pipe fragment	1
Presidio	BBDA; 1, 1A, 2, and 2A; Trench Area 1; Test Pit BBITP102 (representative collection) for URS	38457	green glass Coke bottle, complete	1
Presidio	BBDA; 1, 1A, 2, and 2A; Trench Area 1; Test Pit BBITP102 (representative collection) for URS	38457	clear glass soda bottle, complete, no label or writing on sides; bottom of body is divided into 8 "sides"; embossed on base: "12", a diamond superimposed over an oval (letter O)(symbol of the Owens-Illinois glass company, Toledo, OH)	1
Presidio	BBDA; 1, 1A, 2, and 2A; Trench Area 1; Test Pit BBITP102 (representative collection) for URS	38457	clear glass soda bottle, nearly complete (part of neck is broken off); similar in shape to above bottle but not as tall; embossed on base: "H-257" (in center) and below that, the letter "H" over the letter "A" (symbol of the Hazel-Atlas glass company, Whe	1
Presidio	BBDA; 1, 1A, 2, and 2A; Trench Area 1; Test Pit BBITP102 (representative collection) for URS	38457	clear glass bottle, nearly complete (part of neck is broken off); bottom of body is divided into 10 "sides"; on base: "9", the letter "H" over the letter "A" (symbol of the Hazel-Atlas glass company, Wheeling, WV) (in center); and (along bottom) "0-9161"	1
Presidio	BBDA; 1, 1A, 2, and 2A; Trench Area 1; Test Pit BBITP102 (representative collection) for URS	38457	green glass Coke bottle fragment: all of base and some of the body, "SAN FRANCISCO CAL" on bottom of base	1
Presidio	BBDA; 1, 1A, 2, and 2A; Trench Area 1; Test Pit BBITP102 (representative collection) for URS	38457	amber bottle fragment- top and neck portion with just the slightest part of the body remaining; plastic orange cap is present and twists on and off	1

Summary of Artifacts Recovered During all Investigative Activities for Baker Beach Disturbed Areas 1, 1A, 2 and 2A

Location	Area of Investigation	Collection Date	Description	Count
Presidio	BBDA; 1, 1A, 2, and 2A; Trench Area 1; Test Pit BBITP102 (representative collection) for URS	38457	clear glass bottle base, nearly complete, embossed on bottom: "…glas" in cursive on top; "STORE" in large letters in center, and "23", the diamond-superimposed-over-an-oval symbol mentioned earlier, and the number "3" along the bottom	1
Presidio	BBDA; 1, 1A, 2, and 2A; Trench Area 1; Test Pit BBITP102 (representative collection) for URS	38457	clear glass bottle base, complete base, embossed on bottom: "4-9" on top, the letter "H" over the letter "A" (symbol of the Hazel-Atlas glass company, Wheeling, WV) in the center; and along the bottom: "K 625"	1
Presidio	BBDA; 1, 1A, 2, and 2A; Trench Area 1; Test Pit BBITP102 (representative collection) for URS	38457	small clear glass bottle, complete, for medicine or cosmetics?, wrapped around the bottom half of the body is a slightly (1 mm) thicker raised area	1
Presidio	BBDA; 1, 1A, 2, and 2A; Trench Area 1; Test Pit BBITP102 (representative collection) for URS	38457	small blue glass Noxzema cosmetics jar, lid missing but otherwise complete; the number 2 and the word "NOXZEMA" embossed on base, with the "Z" being very large and dividing the word in half ("NOX" on one side; "EMA" on the other)	1
Presidio	BBDA; 1, 1A, 2, and 2A; Trench Area 1; Test Pit BBITP102 (representative collection) for URS	38457	small blue glass Vicks cosmetic/medicine jar, lid missing but otherwise complete; embossed on bottom: "VICKS" (around top of base); a triangle (in center); and "VA-TRO-NOL" along bottom	1
Presidio	BBDA; 1, 1A, 2, and 2A; Trench Area 1; Test Pit BBITP102 (representative collection) for URS	38457	small blue glass medicine jar, lid missing but otherwise complete; embossed in the center of the base bottom is the letter M	1
Presidio	BBDA; 1, 1A, 2, and 2A; Trench Area 1; Test Pit BBITP102 (representative collection) for URS	38457	small white glass bottle, lid missing but otherwise complete; on bottom of base: "MENTHOLATUM 5 REG. TRADE MARK"	1
Presidio	BBDA; 1, 1A, 2, and 2A; Trench Area 1; Test Pit BBITP102 (representative collection) for URS	38457	small clear glass bottle, lid missing but otherwide complete, no markings except on bottom of base: "DR. LYONS TOOTH POWDER" around circ. of base, with the number 5, the letter A in a circle, and the number 43 along the center	1

Summary of Artifacts Recovered During all Investigative Activities for Baker Beach Disturbed Areas 1, 1A, 2 and 2A

Location	Area of Investigation	Collection Date	Description	Count
Presidio	BBDA; 1, 1A, 2, and 2A; Trench Area 1; Test Pit BBITP102 (representative collection) for URS	38457	clear glass bottle neck/top fragment	1
Presidio	BBDA; 1, 1A, 2, and 2A; Trench Area 1; Test Pit BBITP102 (representative collection) for URS	38457	dark blue bottle glass; fragment of the base and some of the body; the letters “OPS” are visible on the base	1
Presidio	BBDA; 1, 1A, 2, and 2A; Trench Area 1; Test Pit BBITP102 (representative collection) for URS	38457	clear glass bottle neck/top fragment; melted/burned and as a resulted is twisted and distorted	1
Presidio	BBDA; 1, 1A, 2, and 2A; Trench Area 1; Test Pit BBITP102 (representative collection) for URS	38457	clear glass base fragment	1
Presidio	BBDA; 1, 1A, 2, and 2A; Trench Area 1; Test Pit BBITP102 (representative collection) for URS	38457	clear glass body fragment; melted/burned, with horiz. Lines resembling those of a potter’s wheel	1
Presidio	BBDA; 1, 1A, 2, and 2A; Trench Area 1; Test Pit BBITP102 (representative collection) for URS	38457	green glass soda bottle body fragment; red and yellow paint residue present; the word “ROYAL” is etched into the body and was probably painted	1
Presidio	BBDA; 1, 1A, 2, and 2A; Trench Area 1; Test Pit BBITP102 (representative collection) for URS	38457	clear glass base (?) fragment; thick (approx. 5 mm) with a raised bubble-like pattern on upper surface	1
Presidio	BBDA; 1, 1A, 2, and 2A; Trench Area 1; Test Pit BBITP102 (representative collection) for URS	38457	clear glass fragment; about the same thickness as above specimen, but no rim or base visible; entire surface is cracked/crazed with bubble-like pattern	1

Summary of Artifacts Recovered During all Investigative Activities for Baker Beach Disturbed Areas 1, 1A, 2 and 2A

Location	Area of Investigation	Collection Date	Description	Count
Presidio	BBDA; 1, 1A, 2, and 2A; Trench Area 1; Test Pit BBITP102 (representative collection) for URS	38457	porcelain mug, plain white, complete, on bottom of mug in black ink: "TEPCO U.S.A. CHINA"	1
Presidio	BBDA; 1, 1A, 2, and 2A; Trench Area 1; Test Pit BBITP102 (representative collection) for URS	38457	thick white mug, nearly complete (part of the body is missing so it may or may not have had a handle); on bottom of mug in blue ink, written in a circle: "ROYAL CHINA INC. SEBRING, OHIO"	1
Presidio	BBDA; 1, 1A, 2, and 2A; Trench Area 1; Test Pit BBITP102 (representative collection) for URS	38457	thick white mug, approx. half of the mug (part of the body is missing so it may or may not have had a handle); base is mostly gone but a hint of blue ink (and its size) suggests it is a mug identical to the example above	1
Presidio	BBDA; 1, 1A, 2, and 2A; Trench Area 1; Test Pit BBITP102 (representative collection) for URS	38457	thick white mug, approx. half of the mug (part of the body is missing so it may or may not have had a handle); base is mostly gone but the letters "CO" in blue ink on the base bottom (and its size) suggests it is a mug identical to the TEPCO example a	1
Presidio	BBDA; 1, 1A, 2, and 2A; Trench Area 1; Test Pit BBITP102 (representative collection) for URS	38457	rim and body fragment of same type of mug as noted in above examples; base missing	1
Presidio	BBDA; 1, 1A, 2, and 2A; Trench Area 1; Test Pit BBITP102 (representative collection) for URS	38457	mug body fragment of same type as noted in above examples	1
Presidio	BBDA; 1, 1A, 2, and 2A; Trench Area 1; Test Pit BBITP102 (representative collection) for URS	38457	gravy boat fragment- nearly half of a complete specimen- with half of base, rim, and body present; handle broken off; on bottom of base in blue ink " U.S.Q.M…."; below that: "Shenango"; "New Castle,PA"; same thickness as mugs noted above	1
Presidio	BBDA; 1, 1A, 2, and 2A; Trench Area 1; Test Pit BBITP102 (representative collection) for URS	38457	mug or cup fragment- half of base and a fragment of the body; on base in blue ink: "U.S.Q.R……"; below that: "W 431 QM-……"; below that: "4-28-41"; same thickness as above mentioned gravy boat and mug fragments	1

Summary of Artifacts Recovered During all Investigative Activities for Baker Beach Disturbed Areas 1, 1A, 2 and 2A

Location	Area of Investigation	Collection Date	Description	Count
Presidio	BBDA; 1, 1A, 2, and 2A; Trench Area 1; Test Pit BBITP102 (representative collection) for URS	38457	plate fragment, same thickness as all above mentioned articles; plate is divided into at least 3 separate portions; white; on base in red ink: "TEPCO VITRIFIED …….; MADE IN ……."	1
Presidio	BBDA; 1, 1A, 2, and 2A; Trench Area 1; Test Pit BBITP102 (representative collection) for URS	38457	large bowl fragment (slightly less than half); incl. some base and rim; no inscriptions/maker's marks	1
Presidio	BBDA; 1, 1A, 2, and 2A; Trench Area 1; Test Pit BBITP102 (representative collection) for URS	38457	bowl fragment, smaller sized than above example but same thickness; incl. some base and rim but no identifying marks	1
Presidio	BBDA; 1, 1A, 2, and 2A; Trench Area 1; Test Pit BBITP102 (representative collection) for URS	38457	vase or pitcher fragment, incl. portion of rim but no base; white, slightly less thick than above examples (approx. 4 mm thick as opposed to 5 mm); one nonrounded corner suggests spout; no identifying marks	1
Presidio	BBDA; 1, 1A, 2, and 2A; Trench Area 1; Test Pit BBITP102 (representative collection) for URS	38457	white bowl fragment of same thickness as above pitcher fragment; some rim and base present but no identifying marks	1
Presidio	BBDA; 1, 1A, 2, and 2A; Trench Area 1; Test Pit BBITP102 (representative collection) for URS	38457	white plate fragment of same thickness as above pitcher and bowl fragment; some rim and base present, plate NOT divided into portions (as the other plate fragment was); no identifying marks	1
Presidio	BBDA; 1, 1A, 2, and 2A; Trench Area 1; Test Pit BBITP102 (representative collection) for URS	38457	plate or shallow bowl fragment, white some rim and base present but no identifying marks; thinnest example of this group (approx. 3 mm)	1
Presidio	BBDA Trench 2, West End Trash Deposit	38470	Cow rib (saw cut)	1
Presidio	BBDA Trench 2, West End Trash Deposit	38470	Cream bottle, green lettering; paint washed off but writing engraved on bottle exterior; "GREEN GLEN DAIRY SAN FRANCISCO" on front; "Life in San Francisco INCLUDES DINING OUT OFTEN" on back	1

Summary of Artifacts Recovered During all Investigative Activities for Baker Beach Disturbed Areas 1, 1A, 2 and 2A

Location	Area of Investigation	Collection Date	Description	Count
Presidio	BBDA Trench 2, West End Trash Deposit	38470	clear glass bottle base; embossed on bottom are: the letter "H" over an "A" (symbol of the Hazel-Atlas glass company, Wheeling, WV); the numbers "5 5 3 3" below the A, the letter "L" below the #s, and the number "6" below the L	1
Presidio	BBDA Trench 2, West End Trash Deposit	38470	top, neck, and upper body fragment of green soda bottle (coke bottle?)	1
Presidio	BBDA Trench 2, West End Trash Deposit	38470	bronze pipe fragment	1
Presidio	BBDA Trench 2, West End Trash Deposit	38470	clear glass bottle base; embossed on bottom are: the letter "N" in a square; the number "23" at the same level as the N but towards the right side; and the number "8" in the center bottom of the base	1
Presidio	BBDA Trench 2, West End Trash Deposit	38470	purple glass bottle base; oval-shaped, poss. medicine or liquor bottle; base has the number "10" embossed on bottom; outline of circle on bottom center of base	1
Presidio	BBDA Trench 2, West End Trash Deposit; Back fill pile	38471	wood fragment, some mold, white paint remains	1
Presidio	BBDA Trench 2, West End Trash Deposit; Back fill pile	38471	ferrous metal; possible bottle top, badly corroded	1
Presidio	BBDA Trench 2, West End Trash Deposit; Back fill pile	38471	clear glass bottle base; embossed on bottom are: (curved around top) "23", a diamond superimposed over an oval (letter O)(symbol of the Owens-Illinois glass company, Toledo, OH), and an encircled letter, possibly an "S" or a "G"; a large "DM" in the cente	1
Presidio	BBDA Trench 2, West End Trash Deposit	38470	iron spike, corroded	1
Presidio	BBDA Trench 2, West End Trash Deposit	38470	amber bottle fragment: most of base and part of body; embossed up the side is visible: ""….ING Co."; below that (if held sideways): "…ND's"; below that, "…..ER" stands for: CALIFORNIA BOTTLING Co; JOHN WIELAND'S; EXPORT BEER. 1894-1900 Red Amber (Wilson 1968)	1
Presidio	BBDA Trench 2, West End Trash Deposit	38470	clear glass body fragments	2
Presidio	BBDA Trench 2, West End Trash Deposit	38470	lead wire cover/small pipe fragment, bent	1
Presidio	BBDA Trench 2, West End Trash Deposit	38470	small clear glass Listerine bottle with black plastic cover still on and yellow-colored liquid still inside (about 1/3 full); on bottom of body: "LAMBERT PHARMACAL Co"	1

Summary of Artifacts Recovered During all Investigative Activities for Baker Beach Disturbed Areas 1, 1A, 2 and 2A

Location	Area of Investigation	Collection Date	Description	Count
Presidio	BBDA Trench 2, West End Trash Deposit	38470	medium-sized clear glass bottle with metal cap molded/melted on and oxidizing; a small amount of yellowish liquid remains in bottle (just enough to cover the bottom); "ABSORBINE JR. 4 FL" circles just below the neck of the bottle	1
Presidio	BBDA Trench 2, West End Trash Deposit	38470	asphalt roofing shingles, black and crumbly, with green grainy particles (paint remnant?) stuck to one side of most of them	5
Presidio	BBDA Trench 2, West End Trash Deposit	38470	green glass soda bottle fragment- most of bottom portion; red and yellow paint is smeared on some of the body; along bottom is embossed: "PROPERTY OF (?)NEHI BOTTLING CO"; on bottom of base is embossed: "20", the diamond-superimposed-over-an-oval symbol,	1
Presidio	BBDA Trench 2, West End Trash Deposit	38470	clear glass bottle fragment- all of neck/rim, part of body, no identifying marks; poss. milk/cream bottle	1
Presidio	BBDA Trench 2, West End Trash Deposit	38470	small orange medicine bottle with top rusted on; embossed on bottom is the letter H over the letter A (symbol of the Hazel-Atlas glass company, Wheeling, WV) and a very small 5	1
Presidio	BBDA Trench 2, West End Trash Deposit	38470	clear glass medicine/cosmetic jar; complete; no inscriptions/maker's mark save a number 9 (or 6) on bottom of jar	1
Presidio	BBDA Trench 2, West End Trash Deposit	38470	clear glass bottle fragment- rim/neck and body fragment	1
Presidio	BBDA Trench 2, West End Trash Deposit	38470	clear glass bottle fragment with embossed wave design around most of fragment	1
Presidio	BBDA Trench 2, West End Trash Deposit	38470	clear glass bottle fragments	2
Presidio	BBDA Trench 2, West End Trash Deposit	38470	2 half-pint cream bottles, clear glass; "CLARA-CAL, A COOPERATIVE ORGANIZATION OF BAY AREA DAIRYMEN"; below that, a picture of the head of a cow in a circle; on the back side of the bottle: "USE MORE CLARA-CAL MILK; DELICIOUS: as a beverage (this is in cursive)	2
Presidio	BBDA Trench 2	38447	leather boot, badly corroded, just the sole and heel portions	1
Presidio	BBDA Trench 2	04/2005.	ferrous metal utility pipes (stays?); both have hook-shaped ends, badly corroded	2
Presidio	BBDA Trench 2	04/2005.	clear glass bottle body fragment	1
Presidio	BBDA Trench 2	04/2005.	2 half-pint cream bottles, clear glass; "CLARA-CAL, A COOPERATIVE ORGANIZATION OF BAY AREA DAIRYMEN"; below that, a picture of the head of a cow in a circle; on the back side of the bottle: "USE MORE CLARA-CAL MILK; DELICIOUS: as a beverage (this is in cursive)	2

Summary of Artifacts Recovered During all Investigative Activities for Baker Beach Disturbed Areas 1, 1A, 2 and 2A

Location	Area of Investigation	Collection Date	Description	Count
Presidio	BBDA Trench 2	04/2005.	clear glass bottle fragment, upper portion (neck and part of body), no remaining maker's marks or paint	1
Presidio	BBDA Trench 2	04/2005.	1 half-pint cream/milk bottle, clear glass; etched (once painted in red, but the paint is gone): "DEL MAR CREAMERY S.F. AND S.M. CAL." on front; on back, a picture of a hand holding a creamer, pouring cream into a coffee cup with steam rising out of it;	1
Presidio	BBDA Trench 2	04/2005.	Beer cans; Brown Derby Pilsner brand, 12 fl. oz can; in various stages of rust and crushedness	4
Presidio	BBDA Trench 2	04/2005.	Beer cans; Pabst Blue ribbon brand, 12 fl. oz can; one is rusty but barely crushed; the other is not as rusty but very crushed	2
Presidio	BBDA Trench 2	04/2005.	Beer can; Acme brand (black can with black label on white and a leafy decoration); slightly crushed but not much rust; 12 fl oz.	1
Presidio	BBDA Trench 2	04/2005.	Beer can, Regal Pale Ale brand, 12 fl oz; slightly crushed but minimally rusty	1
Presidio	BBDA Trench 2	04/2005.	amber beer bottle, complete except for a lid/cap, no label or distinguishing markings; on bottom of base is the number 7 below the diamond-in-oval symbol and the letter J	1
Presidio	BBDA Trench 2	04/2005.	clear glass bottle, complete except for a lid/cap, no label or distinguishing markings; on bottom of base: the letter N in a square (symbol of the Obear-Nester glass company, East St. Louis, IL); "12", and (below them) "9."	1
Presidio	BBDA Trench 2	04/2005.	brick fragment (about half); orange in color with lots of cracks and pebble inclusions; some traces of green paint are present throughout the specimen	1
Presidio	BBDA 1, 1A, 2, and 2A; Trench Area 2A- slope (representative collection); for URS	38456	clear glass wine bottle, whole, with ferrous top rusted on; embossed on bottom: "20"; a diamond superimosed over an oval (letter O) (symbol of the Owens-Illinois glass company, Toledo, OH); "4", "5B", "1685-W"	1
Presidio	BBDA 1, 1A, 2, and 2A; Trench Area 2A- slope (representative collection); for URS	38456	clear glass beverage bottle; top missing but otherwise complete; has 20 "sides"; on bottom of base: "1088" (on top) and "7" (on bottom)	1
Presidio	BBDA 1, 1A, 2, and 2A; Trench Area 2A- slope (representative collection); for URS	38456	clear glass bottle fragment- bottom half and part of neck; embossed on body: "MOTOR OIL"; along bottom: "SHIELDS, HARPER & CO OAKLAND-LOS ANGELES-SEATTLE"; on back: "FILL TO LINE AT ARROW POINT"; written sideways up neck: "ONE ……"; on bottom of base: "	1
Presidio	BBDA 1, 1A, 2, and 2A; Trench Area 2A- slope (representative collection); for URS	38456	amber glass bottle, complete (except for a top); on bottom of base: "L-54"; below that: "351 CC"; below that: "US PAT. 2097912"; below that, an anchor logo with an "H" superimposed over it (symbol of the Anchor Hocking Corporation, Lancaster, OH and other	1

Summary of Artifacts Recovered During all Investigative Activities for Baker Beach Disturbed Areas 1, 1A, 2 and 2A

Location	Area of Investigation	Collection Date	Description	Count
Presidio	BBDA 1, 1A, 2, and 2A; Trench Area 2A- slope (representative collection); for URS	38456	bottom half of a green Dr. Pepper bottle	1
Presidio	BBLR Trench 4 (Expansion), North Side, Red chert interface	38477	nearly complete brick; only one part of one corner is missing; orange in color with lots of cracks and pebble inclusions	1
Presidio	BBLR Trench 4 (Expansion), North Side, Wood/platform interface	38478	metal spike or nail, badly corroded	1
Presidio	BBLR Trench 4 (Expansion), North Side, Wood/platform interface	38478	clear glass bottle body fragments	2
Presidio	BBLR Trench 4 (Expansion), North Side, Wood/platform interface	38478	clear glass bottle fragment- upper portion (neck and part of body); no paint or maker's marks present; large opening suggests dairy bottle	1
Presidio	BBLR Trench 4 (Expansion), North Side, Wood/platform interface	38478	clear glass bottle fragment- upper portion (neck and part of body); no paint or maker's marks present; smaller mouth suggests liquor or medicine bottle	1
Presidio	BBLR Trench 4 (Expansion), South Side, Sample	38477	red chert core fragment	1
Presidio	BBLR Trench 4 (Expansion), South Side, Sample	38477	metal spikes/nails, badly corroded	3
Presidio	BBLR Trench 4 (Expansion), South Side, Sample	38477	Black glass covered in rust	1
Presidio	Battery West Mortar Batteries, Trench 4 (Expansion), South Side, Top of sand/ bottom of dark fill + metal detector finds	38484	nails/spikes, badly corroded	5
Presidio	Battery West Mortar Batteries, Trench 4 (Expansion), South Side, Top of sand/ bottom of dark fill + metal detector finds	38484	ferrous metal fragments (pieces of nails?); badly corroded	2

Summary of Artifacts Recovered During all Investigative Activities for Baker Beach Disturbed Areas 1, 1A, 2 and 2A

Location	Area of Investigation	Collection Date	Description	Count
Presidio	Battery West Mortar Batteries, Trench 4 (Expansion), South Side, Top of sand/ bottom of dark fill + shovel skim finds	38484	purple glass bottle fragment with portion of rim present	1
Presidio	Battery West Mortar Batteries, Trench 4 (Expansion), South Side, black (dark fill) fill above sand pad + backhoe finds	38485	clear glass bottle fragment, upper portion (neck and part of body), no remaining maker's marks or paint	1
Presidio	Battery West Mortar Batteries, Trench 4 (Expansion), South Side, black (dark fill) fill above sand pad + backhoe finds	38485	ferrous metal bottle cap, nearly complete, badly corroded	1
Presidio	Battery West Mortar Batteries, Trench 4 (Expansion), South Side, black (dark fill) fill above sand pad + backhoe finds	38485	nails, badly corroded	3
Presidio	Battery West Mortar Batteries, Trench 4 (Expansion), South Side, black (dark fill) fill above sand pad + backhoe finds	38485	ferrous metal fragment, badly corroded	1
Presidio	Battery West, Trench 4 (Expansion), South Side, Top of sand/bottom of dark fill + shovel skim finds	38484	thin black rubber (?) strips, broken into several pieces	6
Presidio	BBLR Trench 4 (Expansion), Southside, sand interface to dark soil	38477	large metal spike/pipe, badly corroded	1
Presidio	BBLR Trench 4 (Expansion), Southside, sand interface to dark soil	38477	badly corroded nails/nail fragments	27
Presidio	BBLR Trench 4 (Expansion), Southside, interface of black soil/ sand layer	38477	metal spike/large nail, badly corroded	1

Summary of Artifacts Recovered During all Investigative Activities for Baker Beach Disturbed Areas 1, 1A, 2 and 2A

Location	Area of Investigation	Collection Date	Description	Count
Presidio	BBLR Trench 4 (Expansion), Southside, interface of black soil/ sand layer	38477	nails, badly corroded	2
Presidio	BBLR Trench 4 (Expansion), South side, interface of black soil/ sand layer	38477	unidentified ferrous metal piece, round and small (approx. 5 mm), badly corroded, poss. button/snap?	1
Presidio	BBLR Trench 4 (Expansion), North side, interface of chert/black soil layer	38477	brick fragment, dark red, about 1/8 of brick	1
Presidio	BBLR Trench 4 (Expansion), North side, interface of chert/black soil layer	38477	large metal pipe fragment, badly rusted, curves upward in a “J” shape	1
Presidio	BBLR Trench 4 (Expansion), North side, interface of chert/black soil layer	38477	building ceramic fragments; light orange in color, full of pebble inclusions	2
Presidio	BBLR Trench 4 (Expansion), North side, interface of chert/black soil layer	38477	lead pipe (?) fragment, curved, fair condition	1
Presidio	BBLR Trench 4 (Expansion), bottom of trench	05/2005.	lt.blue plastic plant tag, approx. 4 cm x 1 cm x 1 mm; written in black sharpie on front: “LIZARD TA…..”; below that, “FT. POINT”	1
Presidio	BBLR Trench 4 (Expansion), bottom of trench	05/2005.	ceramic insulator fragments, white, approx. 2 cm circ., middle-sized piece has .”..JOHNSON” etched in black ink on front	3
Presidio	BBLR Trench 4 (Expansion), bottom of trench	05/2005.	small concrete fragment, with hexagonal white ceramic tile attached to top	1
Presidio	BBLR Trench 4 (Expansion), bottom of trench	05/2005.	large concrete fragment, with white ceramic tile fragment attached to top	1
Presidio	BBLR Trench 4 (Expansion), bottom of trench	05/2005.	red brick fragments	4
Presidio	BBLR Trench 4 (Expansion), bottom of trench	05/2005.	green glass bottle body fragments	2
Presidio	BBLR Trench 4 (Expansion), bottom of trench	05/2005.	lt. blue glass bottle body fragment; visible on fragment is the number 7(?) in a square	1
Presidio	BBLR Trench 4 (Expansion), bottom of trench	05/2005.	porcelain plate rim fragment, white with a thick maroon stripe along edge and a thinner maroon stripe below it	1

Summary of Artifacts Recovered During all Investigative Activities for Baker Beach Disturbed Areas 1, 1A, 2 and 2A

Location	Area of Investigation	Collection Date	Description	Count
Presidio	BBLR Trench 4 (Expansion), bottom of trench	05/2005.	nail, badly corroded	1
Presidio	BBLR Trench 4 (Expansion), bottom of trench	05/2005.	small glass medicine bottle with top rusted/secured on; remnants of white paper label present on front of bottle but illegible	1
Presidio	BBDA Trench 5	38477	white glazed ceramic utility fragment	1
Presidio	BBDA Trench 5	38477	green Coca Cola bottle, complete	1
Presidio	BBDA Trench B, 0-1' depth	38467	small amber glass medicine bottle, complete	1
Presidio	BB Landfill Removal; Excavation of magazine	38477	ferrous metal object, round, possible bottle top, badly corroded; white plastic label on top; in red ink along upper part: "Catch Our Spirit:, in center: a black "CT" symbol, along bottom of label in blue: "County Transit"	1
Presidio	BBDA, from deep concentration adjacent to Feature 21	05/2005.	red brick fragments	8
Presidio	BBDA, from deep concentration adjacent to Feature 21	05/2005.	one piece of black slag, with one thin piece broken off	2
Presidio	Battery Godfrey	38406	large clear glass jar, barrel-shaped, lid missing but otherwise complete and in good condition; on bottom of base: "425-65"; "13", "4", and "Ball" (in cursive)	1
Presidio	Battery Godfrey	38406	clear drinking glass, complete, on bottom: "C", two intersecting diamonds, and "4" (along top), "6" (at bottom) and "6181" (above it)	1
Presidio	Battery Godfrey	38406	green Coca Cola bottle, complete	1
Presidio	Battery Godfrey	38406	2 clear glass Dr. Pepper bottles, complete, on back of both, a clock is pointing to 10, 2, and 4	2
Presidio	Battery Godfrey	38406	clear glass bottle, complete, for cream or milk, half-pint on front in green letters: "GREEN GLEN DAIRY SAN FRANCISCO"; on back in green letters: "WHY COOK AT HOME? Restaurant (in cursive); (illegible) VARIETY; (illegible) CLEAN TASTE"	1
Presidio	Battery Godfrey	38406	thick (approx. 1 cm) black glass fragment, poss. fragment of safety glass?	1
Presidio	Battery Godfrey	38406	ferrous metal pipe end- open only on one side; badly corroded	1
Presidio	Battery Godfrey	38406	black plastic cover for machine/mechanism; has opening in center with "on" at one end and "off" at the other; two screws present and rusty, center piece with lever to move to "on" or "off" is also present, but separate	2
Presidio	Battery Godfrey	38406	metal/plastic machine/engine pieces, all screws missing and metal parts rusty; appear to be the pieces covered by the black plastic cover, above	4

Location	Area of Investigation	Collection Date	Description	Count
Presidio	Battery Godfrey	38406	two lead light fixtures with round porcelain pieces inside each to hold the light bulb; plastic-coated copper wires protrude from each piece (on one, the covers are black, on the other, white)	2

Appendix F

Merchant Road Tree Island Building History

Memorandum

To: George Ford

CC:

From: Michael Lamb MICHAEL

Date: February 3, 2005

Re: Merchant Road Tree Island Building History

George,

The purpose of this memo is to report on my findings to date on my investigation on the past uses of the buildings that have existed in and around the site that is currently being referred to as the "tree island", between Merchant Road and Lincoln Boulevard in the Fort Scott area of the Presidio. This memo is not meant to replace the more detailed description of the evolution of this area that I will be providing in the near future. This memo will reference a number of attached images that were used in our recent discussion with Quintex on this past January 19, as well as a few additional images to support my thoughts on this matter.

Working with both the maps we have on hand and the Quartermaster Reports I have made these conclusions. It should be noted that moving back between the Quartermaster reports and these drawn images is complicated by the fact that the numbering system for these buildings were changed numerous times through the history of the Presidio. The first drawn map that I used in my Quintex presentation was produced by Major Harts in 1906, see attachment. Within the area of the tree island are two small buildings that are identified as wood frame in the maps legend (not shown in this attachment). A summary drawing of Fort Winfield Scott 1909 shown in Defender of the Gate (D.O.G.), page 559, shows the same two small buildings in the Harts plan and a slightly larger building to the southwest labeled as a guardhouse. It is pure speculation on my part, but after looking at the two small structures in the 1907 Harts plan I wondered if they might have been some guard shack or sentry post based on their location on roads leading from the larger roadway which would become Lincoln Boulevard out to the possibly more sensitive areas in and around the bluffs overlooking Fort Point and the Golden Gate. Seeing the larger building referenced as the Guardhouse in the D.O.G only added to speculation on that possibility.

In the Ft. Winfield Scott Lighting System map of 1917 we see that there are two buildings (80 and 49) within the yet to be expanded tree island and several un-numbered buildings west of Merchant and buildings 70 through 78 and 136 through 143 east of Lincoln. In the Presidio Archaeological Resources (Draft), by W.H. Adams , 1994, Building 80 is referenced as being associated with the 7th Co. Artillery Cantonment, and is labeled as "MILITIA WH". Building 49 shown in the 1917 plan appears to be the one building that survived well into the future, as late as 1951, when it was known as Building 1394 and possibly later still as 1659. The stout construction of this storehouse, 13" concrete walls and slate roof

February 3, 2005

described in the attached Quartermaster report may be the reason that it was able to survive for such a long period after being constructed in 1915. To the east of Lincoln Buildings 70 through 78 were identified as being constructed in 1917 and used for a Camp of Instruction in the Adams report.

The final plan image from 1943 shows a number of structures in the now expanded tree island. These buildings are not identified in any way but one appears to be Building 49 (later 1394) referenced above. Attached is a sheet from the Quartermasters report on Building 1393, a wooden and tar paper mess hall built in 1942 . Again, with speculation, the fact that this building is numbered sequential to 1394 and the photo depicts a tree planting consistent with the island as we believe to have been, strongly suggests that this is one of the now demolished buildings that were in the vicinity of the proposed Merchant Road realignment.

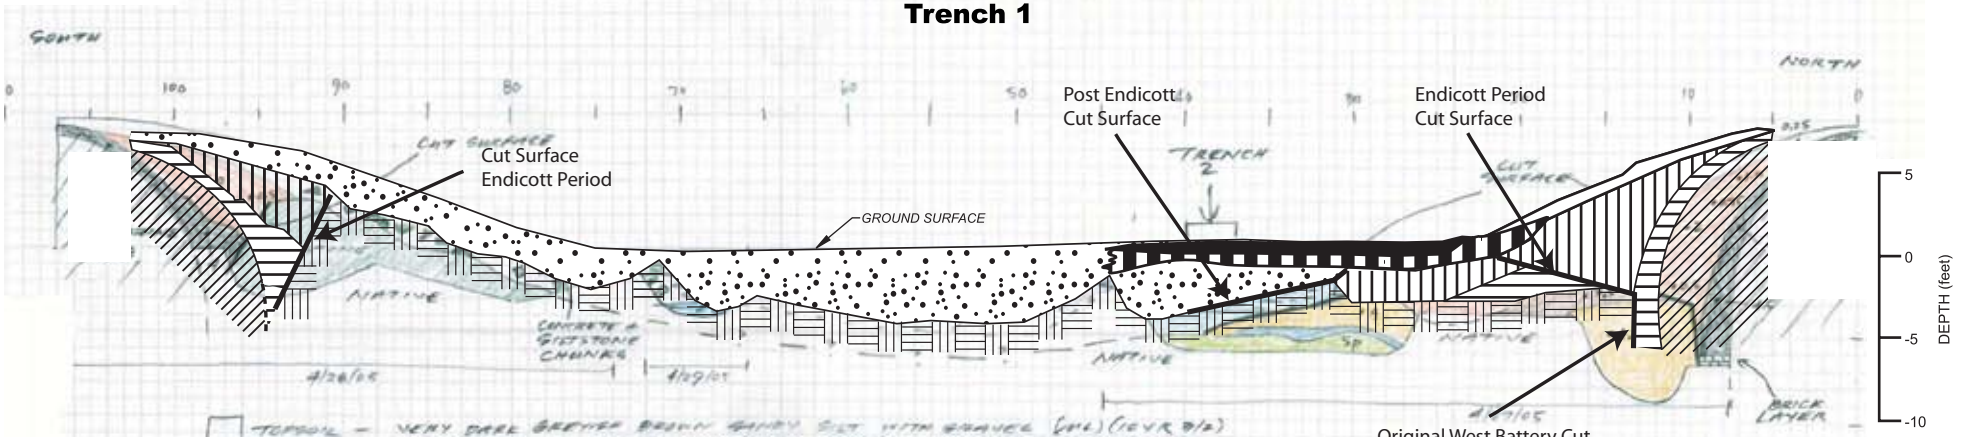
Soil Profile Overlays

Trench 1



TOPSOIL – VERY DARK GREYISH BROWN SANDY SILT WITH GRAVEL (ML)(10YR 3/2) SOFT, DRY TO MOIST, GENERALLY 60% SILT 20% SAND 20% GRAVEL

MIXED CLAY FILL – MIXTURE OF YELLOWISH BROWN (10YR 5/6) AND VERY DARK BROWN (10YR 2/2) LEAN CLAY (CL) SOFT, MOIST., 80% CLAY 20% SILT, OCCASIONALLY SANDY.

CONSTRUCTION CLAY – BLACK LEAN CLAY (CL) (10YR 2/1) HARD TO VERY HARD, MOIST 100% CLAY, COMPACTED ON SIDES OF STRUCTURES.

CONCRETE – MULTIPLE LAIERS OF CONCRETE AND CEMENT GROUT (SOME WITH CELOCURING AGENTS ADDED) PRESUMED TO BE AN OLD WAR CUT AREA

CHERT FILL (1) – DARK REDDISH BROWN WELL GRADED GRAVEL WITH SAND (GW)(5Y 3/2) DENSE, DRY 70% GRAVEL (ANGULAR CHERT TO 1.5"Ø) 20% SAND <10% FINES

CHERT FILL (2) – AS ABOVE, BUT LIGHTER (OLIVE - REDDISH GREY (5Y 5/2)

FILL SAND (1) – VERY DARK GREY POORLY GRADED SAND WITH CLAY INCLUSIONS (SP)(5Y 3/1) LOOSE TO MEDIUM DENSE, DRY TO MOIST. 70% SAND 30% YELLOWISH BROWN CLAY.

FILL SAND (2) – VERY DARK GREY POORLY GRADED SAND (SP)(5Y 3/1) LOOSE TO MEDIUM DENSE. MOIST. 100% SAND.

NATIVE MATERIALS

SILTSTONE – OLIVE GREY SILTSTONE (5Y 5/2) ( ) MODERATELY CONSOLIDATED. CLOSELY FRACTURED LOW HARDNESS. WEAK, DEEPLY WEATHERED

CLAY (1) – VERY DARK GREYISH BROWN LEAN CLAY (CL) (10YR 3/2) HARD. MOIST 80% CLAY 15% SILT 5% VERY FINE GRAINED SAND.

CLAY (2) – YELLOWISH BROWN LEAN CLAY (CL) (10YR 5/6) HARD. MOIST., 100% CLAY, WITH FeO_2 MOTTLE, AND BLACK OXIDATION ALONG FRACTURES. IN PLACES RESEMBLES WEATHERED ROCK.

SAND – DARK GREYISH BROWN SILTY SAND (SM) (2.5Y 4/2) DENSE, WET. 60% VERY FINE SAND 40% SILT/FINES. HAS BEDDING PLANES. THIN LAMINATIONS.

SERPENTINITE – LIGHT OLIVE BROWN (2.5Y 5/2) TO GREENISH GREY (5GY 5/1), MODERATELY CONSOLIDATED. INTENSELY FRACTURED. LOW TO MODERATE HARDNESS. FRIABLE TO WEAK. DEEPLY WEATHERED.

West Battery & Fort Scott Endicott Batteries – Construction, Evolution, and Modifications

Introduction

The line of gun batteries stretching along the Presidio bluffs south and west from the Golden Gate Bridge toll plaza form an 'outdoor museum' of late 19th century fortifications that are rivaled few places elsewhere in the United States. These gun batteries, constructed between 1870 and 1900, show the transitional nature United States defenses at the time when its harbor fortification system was undergoing the change from "storybook castle forts" filled with muzzle loading cannon to modern low-profile earth and concrete fortifications mounting long range, rifled steel guns.

These batteries, referred to as "works" by the U.S. Army Engineers who constructed them, represent not only a time capsule of evolutionary military design, but also include some of the earliest of the modernized American fortifications constructed anywhere in the country.

This investigation into the background, context, construction, alteration, and post-military uses of these batteries has been commissioned by the Presidio Trust. The goal is to develop information that will support URS Corporation's historic resource studies on this area of the Presidio, which are being prepared to provide documentation on historic resources that may be encountered during remedial actions at the Baker Beach Disturbed Areas (BBDAs) in the Presidio of San Francisco. This report on the Presidio batteries will build and expand upon the excellent historic narrative portion of the report "Cultural Resource Baseline and Impact Assessment for the Baker Beach Disturbed Areas" prepared for the Presidio Trust by URS in August 2004.

Major emphasis in the report is given to the history of the 1870s earthworks in the areas designated BBDA 1 (between Batteries Marcus Miller and Boutelle) and BBDA 2A (adjacent to the left flank of Battery Godfrey) because of the documented existence of "Plan of 1870" remnant earthworks and magazines in these areas and the high likelihood of encountering additional resources.

Background and Context

Beginning in 1865, the American military began to reassess its system of harbor defenses. Battlefield lessons learned during the Civil War showed that multi-tiered masonry forts of the style typified by Fort Sumter in Charleston, South Carolina and Fort Pulaski at Savannah, Georgia had proven to be highly vulnerable to attack. Built to design standards that went back to the 1820s, these forts – and about forty other similar works around the United States – were referred to as "Third System forts" because they represented the third generation of American fortification designs. However, during the just-finished war their towering masonry walls had proven to be inviting targets for long range, rifled artillery fire. Instead of withstanding months of siege, some masonry forts had surrendered after only a few days of bombardment. (Fort Pulaski's Confederate defenders held out for only thirty hours before its 7½-foot thick walls were penetrated by Union artillery fire.)

In addition, steam powered warships could race past these masonry fortifications, suffering relatively minor damage to their ironclad hulls, especially when compared to the wind-propelled wooden warships that had been state-of-the-art when the Third System was begun.[1]

The lesson was clear: all these multi storied forts had become obsolete due to advances in military technologies. This included the three-story fort at Fort Point in the Presidio of San Francisco, a work that had only been completed in 1861. These sobering revelations would have impacts both abroad as well as in the United States.

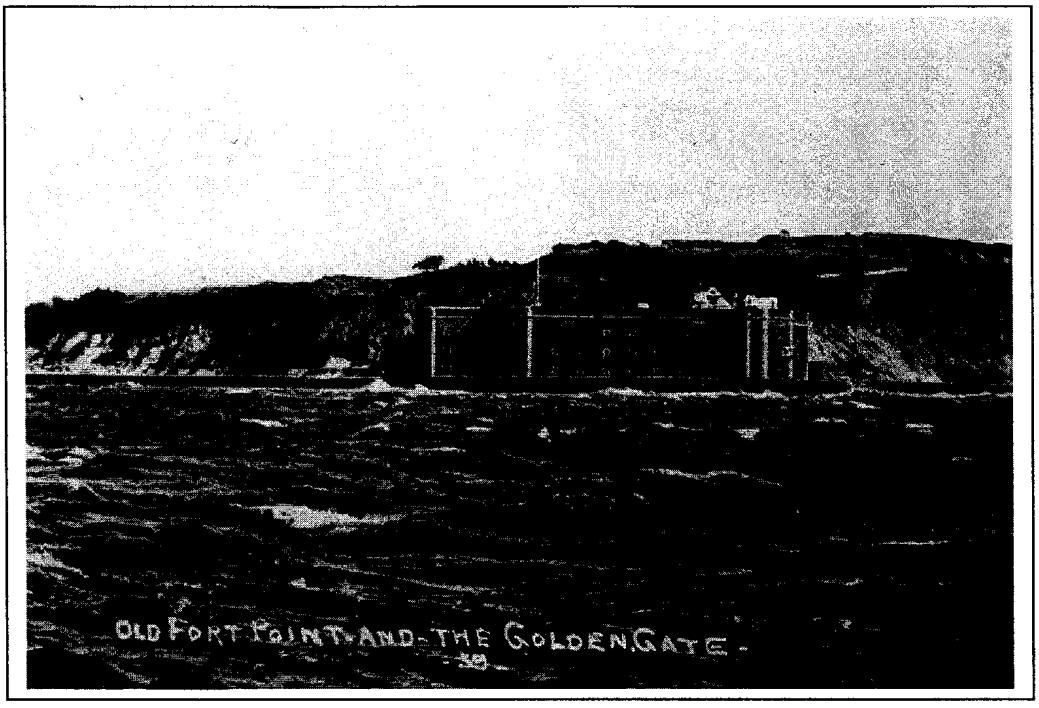

Figure 1. *The visibility and vulnerability of masonry works is illustrated by this view of the fort at Fort Point in the Presidio, c1900.*

Historian E.R. Lewis, the preeminent expert in the evolution of America's coastal defenses, summarized the situation in the late 1860s:

> By 1865 several European nations were already starting to respond to the technical lessons of the Civil War by drafting plans for the construction of entirely new, and extremely expensive, types of permanent harbor defenses armored with great masses of iron, thus beginning a trend in military architecture which was to continue well into the twentieth century, making use in its extreme instances of shore-mounted battleship turrets.
>
> The United States, however, was in no position to commence an extensive new system of harbor defenses. The planning engineers, mindful of the suddenness with which the existing (i.e., Third System) fortifications had been rendered obsolete, were reluctant for technical reasons to turn to elaborate works that might quickly become outmoded, as there was much

> to suggest—correctly, as events proved—a coming period of further rapid advances in artillery. Nor would such an undertaking if proposed have stood much chance of realization, for under the extreme postwar stress on reduced military spending, any appropriations large enough to be meaningful would also have been out of the question.[2]

The U.S. Engineers carried out limited testing with armor plates attached to the faces of existing masonry forts, but with disappointing results. Iron plates frequently split or shattered when hit by projectiles, and the sheer weight of the plates presented huge installation problems. Costs were enormous, and one glaring defect in the plan could not be overlooked; as one historian wrote, "The fort was still a large, obvious target, easy to hit."[3]

Even during these tests, the engineers' thinking was leaning towards a radically new design based upon the simple earthen batteries erected during the Civil War. These emergency works had been constructed of copious amounts of earth and sand cover, and had very low profiles when viewed by an attacking enemy. These improvised fortifications, they noted, had been simple to build, provided excellent protection against enemy fire, and were easy to maintain and repair. Earthworks, they decided, would become be the basis of the next generation of permanent American forts.

In August 1868 the New York Board presented a report concerning the proper profile for postwar barbette batteries. These specifications would be the standards for what came to be called the "Plan of 1870" because of the year of their actual implementation. Historian Erwin Thompson summarized the 1868 Board's findings:

- As a material for parapets, sand was far superior to clay.

- A parapet of sand, 20 feet between the crests supported by a breast-height wall 4 feet thick, would suffice as a minimum.

- A wall in the body of the parapet was not recommended.

- The introduction of iron plates in parapets was inexpedient except in peculiar cases.

- The minimum distance between 15-inch guns should be 34 feet, and the minimum distance between 10-inch guns should be 22 feet.

- The terreplein should not be less than 30 feet in depth.

- There should be a traverse for every two guns that were exposed to direct or oblique fire, and a traverse for every gun subjected to enfilading fire. When practicable, there should be a parados for guns liable to reverse fire.

- Minimum dimensions for a traverse should be 14 feet in height, 12 feet in thickness at the top, and 20 feet in thickness at the bottom.

- Service magazines were indispensable. Good well-rammed concrete was the best material, with no lining.

The board concluded that the use of guns in barbette batteries would be greatly modified in the future, and it recommended that the present carriages and platforms not be constructed in great numbers.[4]

(The last-mentioned carriages and platforms would be a heated topic of research and development. The Ordnance Department was then carrying out experiments on a wide variety of cannon and carriage designs, and one that showed particular potential was the "King's Depressing Carriage." This weapon was, in effect, a conventional muzzle-loading gun mounted on an inclined, sliding steel carriage. After firing, the cannon slid down and out of view for loading. Battery technology for the next half-dozen years

revolved around the anticipated – but never implemented – introduction of the Depressing carriage.)

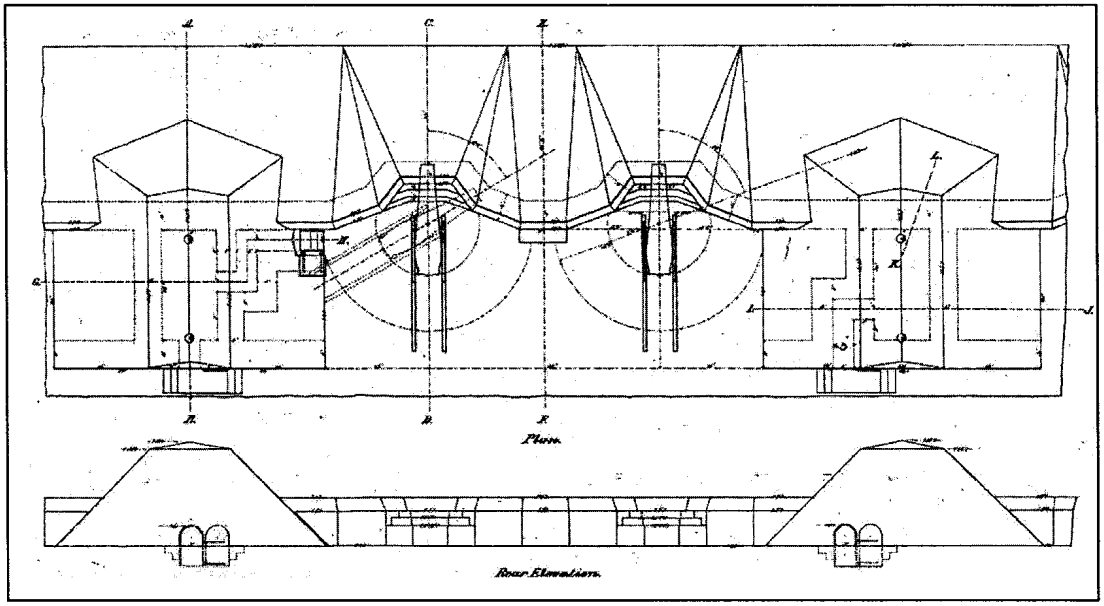

***Figure 2.** Prototypical plan of an earthwork drawing: "Plans Sections and Elevations of a Barbette Batter as Proposed by the Board of Engineers for Fortifications," 1868 (NARA RG77, Dr 155, Sht 14)*

These new American fortifications would be low-rise affairs, extending only a dozen feet at most above grade when viewed from the sea. In order to provide maximum protection for the guns, the weapons would no longer be mounted in the long-unbroken lines of platforms built in the 1850s. It was now planned to emplace the cannon in pairs, and each pair would be separated by artificial earth hills called "traverses." Each traverse was also to house a powder magazine for ammunition storage. Brick-lined, arched tunnels through the earthworks permitted the safe movement of men and supplies during battles.

The new plans also called for a high degree of standardization of weaponry. Instead of the hodge-podge of calibers so common in pre-Civil War forts, the new batteries would mount only four different types of guns: 13-inch smoothbore mortars; 15-inch and 20-inch Rodman pattern smoothbore guns; and a 12-inch rifled Rodman gun still under development. (Neither of the latter two gun types, however, would ever proceed beyond the test phase.)[5]

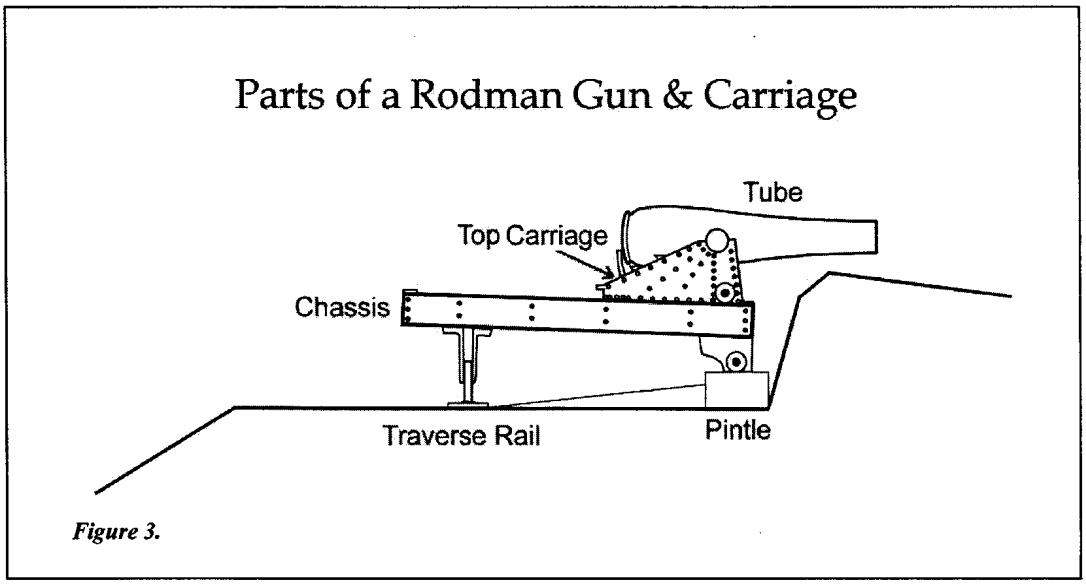

Figure 3.

These batteries would be conspicuously similar in design, varying only slightly between forts due to local material availability and engineer preferences. Guns were to be emplaced entirely *en barbette* (i.e., mounted in the open), sitting atop simple wood or masonry firing platforms and aiming over a breast-high parapet wall directly in front of the gun. Set into this wall were brick steps for the gunners to use when loading powder and shell into the muzzle-loading Rodmans. Guns would be mounted in pairs, with a standard spacing of 34 feet between centerlines. Each pair of guns would be flanked by high earthen hills called "traverses", some measuring 20 feet tall, whose purpose was to prevent an enemy from being able to fire down the entire length of a gun battery (*enfilading fire*). And if by chance a gun was struck by enemy fire, the traverses on either side would restrict any damage to the two guns within the emplacement.

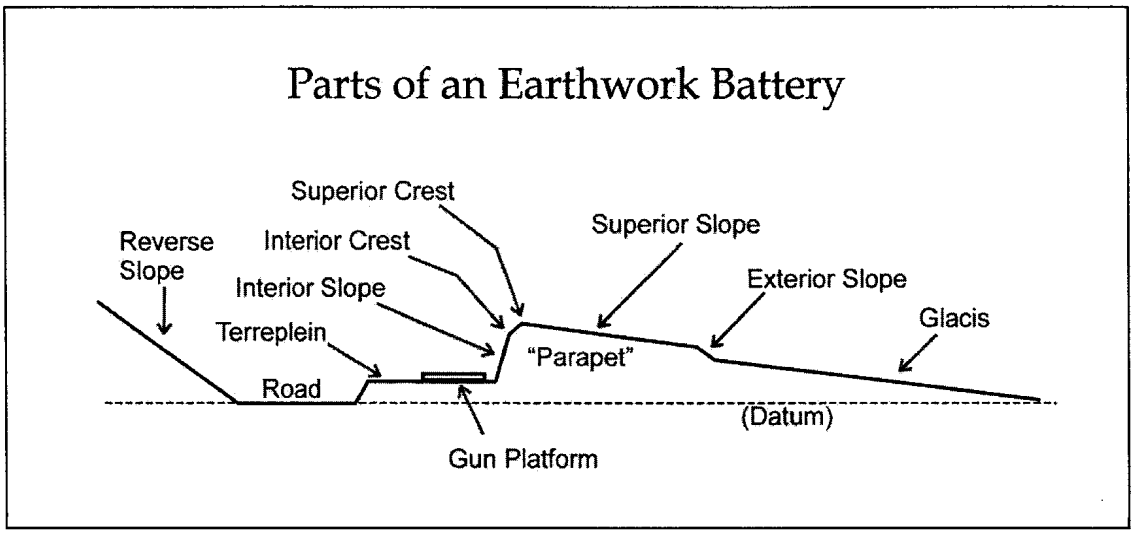

Figure 4. *Section through an emplacement showing names of architectural features.*

Inside each traverse was service powder magazine for storing gun powder for the battery. These service magazines were meant to provide ready-access for the gunners, while much larger "great magazines" located at dispersed locations held central reserves of propellant. Standard interior dimensions for a service magazine was to be 8' x 16', although exact dimensions, entrance locations, and arrangement of approach tunnels would vary. Shot (solid projectiles) and shell (hollow explosive rounds) would usually be stored outside on shot beds close to the guns themselves.

Historian Glen Williford described the flexibility and features of a typical "Plan of 1870" earthwork battery:

> These units could be strung together like beads on a string and lines or batteries could contain twenty or more gun emplacements. … In place of stone or brick, the plans incorporated the use of concrete – its first widespread application in American defenses.
>
> The principal material used for the parapet itself, any glacis in front, for the high traverse covers, and for any rear parados was sand, whose availability and cost advantage were obvious. Some 30 feet of earth or

sand were specified for the depth of the terreplein. Magazines had hung wooden doors, and their interiors had special niches for oil lamps.[6]

Figure5. *A "Plan of 1870" two gun emplacement at East Battery, Fort Scott, c1910. Note the entrance to the service magazine at right. (GOGA, PARC, FOPO Collection.)*

Another feature of the Plan of 1870 works was the incorporation of mortars into the batteries. More than one hundred 13-inch caliber model 1861 mortars had been manufactured during the war, and it was felt their inclusion in the batteries and their plunging arcs of fire would be a perfect addition to the relatively flat trajectory fire of the Rodman cannon.

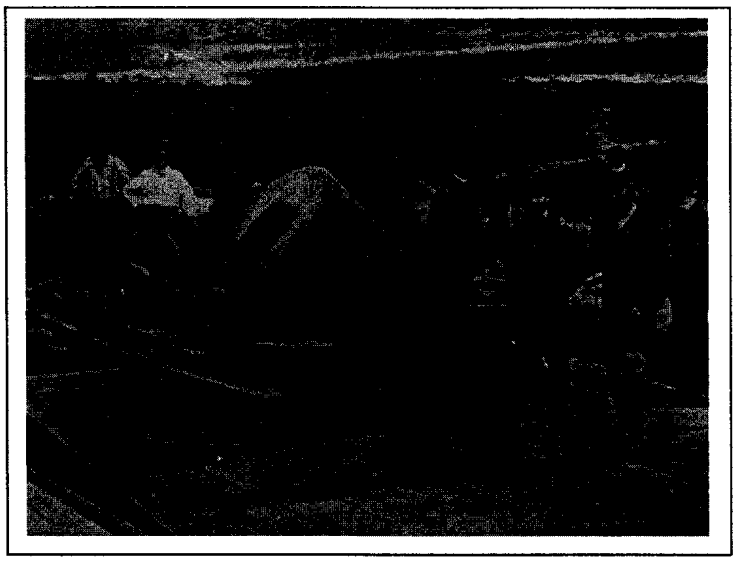

Figure 6. *A Union 13-inch mortar Model 1861 installed during the siege of Petersburg, VA, in 1864. (NARA)*

The drawback to the 13-inch mortar was its relatively short range, slow rate of fire (weapons during this period were still aimed by brute force), and relative inaccuracy. A partial solution was to emplace mortars in groups; firing volleys of mortars at the same target greatly increased the probability of a hit. Two to four mortars per emplacement became the standard, with several mortar emplacements spaced along the length of a battery.

As opposed to the extensive masonry platforms required to support a 15-inch Rodman, mortar beds were relatively simple affairs constructed of overlapping courses of wood topped with iron skid plates. A mortar platform measured 13 feet square and 2 feet thick, and was set nearly flush with the ground. However, only three mortar emplacements around the country were ever armed before funding for the fortification program was cut off. None of these batteries were on the West Coast.[7] Numerous wooden mortar platforms were completed, though, and remained in place for decades afterwards. (See Figure 7.)

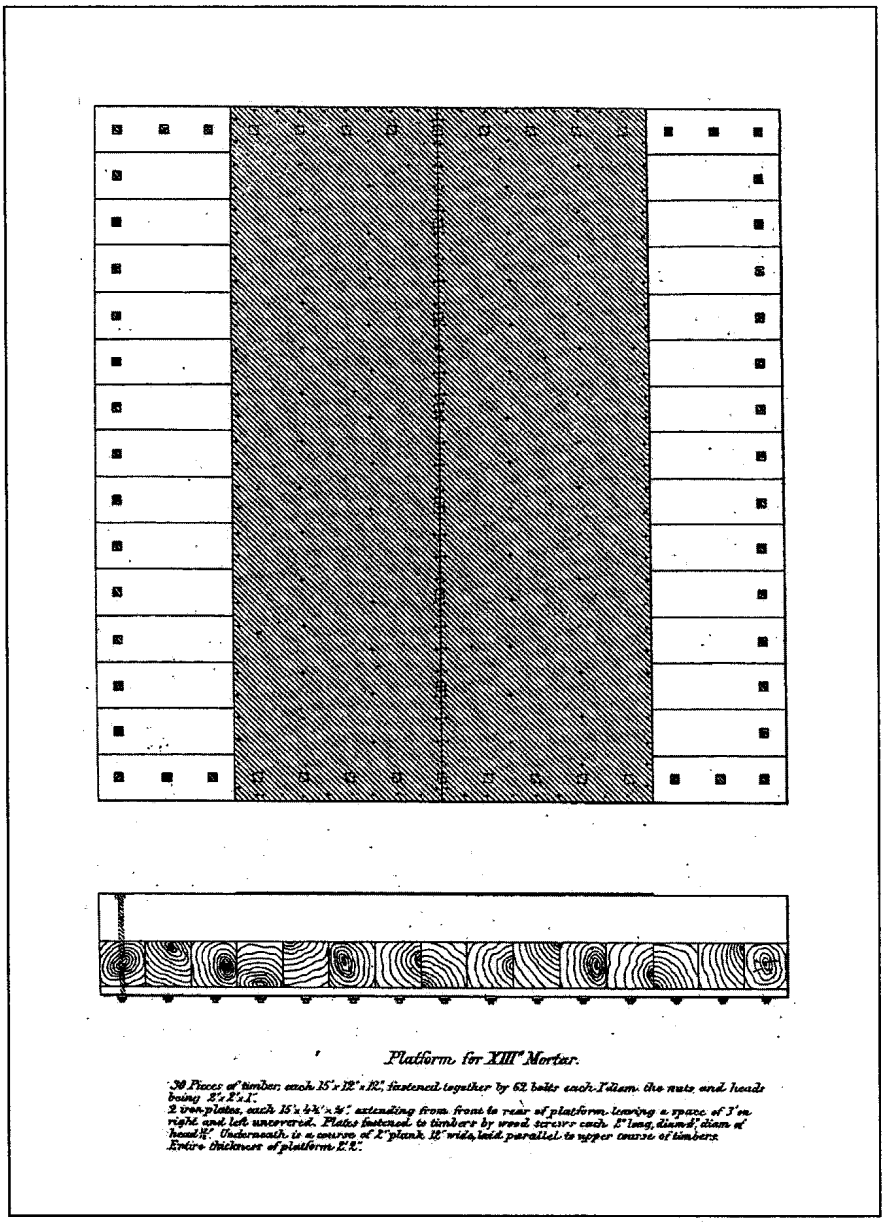

***Figure** 7. Platform for a 13-inch seacoast mortar, 1870. This is the type of platform installed at West Battery. (NARA, RG77)*

In 1870 the army established a special Pacific Board of Engineers to oversee construction of the and modernization of the works around San Francisco Bay, where new batteries were proposed for Fort Point, Alcatraz Island, Angel Island, Lime Point in Marin County, and Point San Jose (Fort Mason) in San Francisco. At Fort Point the Board proposed to construct two lines of batteries on the hills behind the old masonry fort. These works

would be named West Battery and East Battery, reflecting their geographic locations atop the bluffs west and east of the now-obsolete masonry fort.

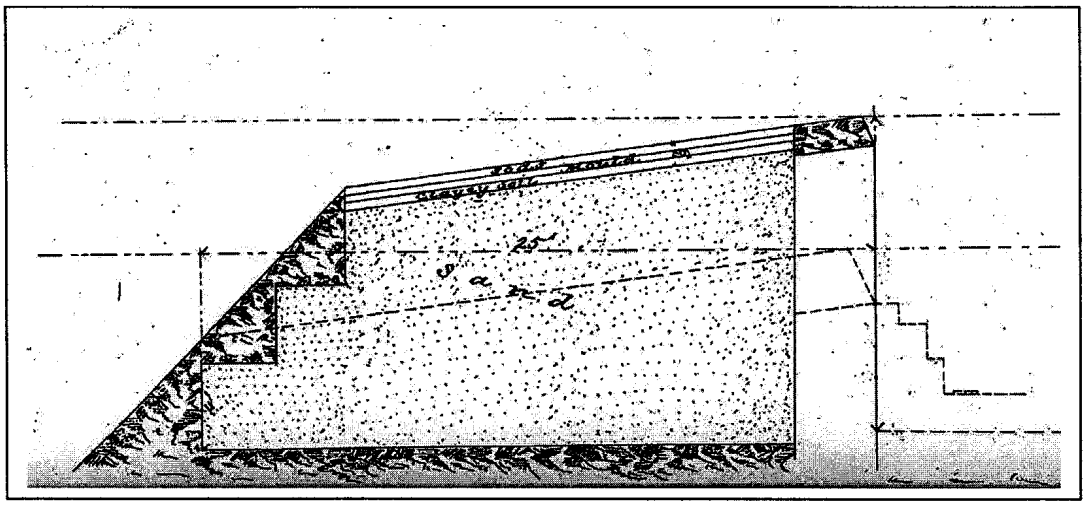

Figure 8. *Detail from drawing titled "Cross-section of Parapets Shewing [sic] Their Construction in Sand," 1871. Note the layers of sods, mould, and clayey soil on superior slope. (NARA, RG77, Dr 155, Sht 17)*

As work progressed on constructing the Plan of 1870 fortifications, financial and political realities began to rear their heads. The Congress began to question the army' continued expenditure of funds on what was becoming increasingly apparent as an obsolescent system of weapons, especially since international advances in weapons, warships and tactics had left the old-pattern American smoothbore guns, no matter what their size, increasingly obsolescent. Rather than allocating money for modern armament and fortifications, Congress decided in 1876 to grant a mere $100,000 for "preservation and repair" of fortifications, and nothing for new construction. In 1877 things became even tighter when Congress adjourned without even passing an army appropriations bill.

For all intents and purposes, work on the Plan of 1870 ceased in 1876. Except for paltry amounts allocated for repair and preservation, no serious expenditures would occur until 1890. Again, Historian Lewis described the situation that followed:

> The deserted batteries were periodically inspected by caretakers, but neither funds nor labor was available to them for arresting the progressive

> deterioration that was to continue into the early 1890s. Third System forts, though patently outdated, and armed for the most part with smoothbore guns of Civil War or earlier vintage, continued to serve, of necessity, as major components of the nation's harbor defenses.
>
> This abortive program nevertheless marked a distinct turning point in American fortification practice, for the technical and tactical concepts on which it was based set a pattern that was to characterize all future harbor defense undertakings in the United States. ... From this time on, a fort was a piece of real estate occupied by a number of dispersed individual batteries. Furthermore, the various items of armament intended for this project, though never in fact adopted, remained under constant development throughout the 1870s and 1880s, with the result that by about 1890 there became available greatly improved weapons around which was conceived the very advanced and extensive generation of defenses that followed.[8]

In some ways, the lull in construction was a boon to U.S. Engineers. Instead of completing and arming the Plan of 1870 works, the army was compelled to wait until the early 1890s to begin construction on the next generation of defensive works, and during this period they were able to reap the windfall of technical developments in artillery and construction made by foreign powers.

During this period, numerous improvements were made that had a direct impact on America's next generation of harbor and coastal defense fortifications:

1. Methods of manufacturing and rifling modern steel artillery pieces evolved to the point where breach loading mechanisms could be introduced, thus allowing the use of highly efficient pointed projectiles and allowing for greater range and accuracy.

2. The development of the 'disappearing carriage' that utilized the recoil energy of a gun to lower itself behind a protective parapet for loading and aiming, without endangering the crew or exposing its location to the enemy
3. The introduction of nitrocellulose- and nitroglycerin-based propellants that yielded higher muzzle velocities to effectively propel pointed projectiles.[9]

In addition, military architecture had made great strides. Advances in concrete construction allowed the building of immensely strong battery structures that could withstand even direct hits by naval artillery. Mechanically operated hoists now lifted projectiles from subterranean magazines to surface gun emplacements, and embryonic telephonic and electrical systems were revolutionizing communications between various parts of the battery, the fort, and even the entire defensive area.

As Lewis summarized:

> Compared to the best of the smoothbore muzzle-loading cannon of the post Civil War period, the new weapons which began to emerge from the developmental stage around 1890 could fire projectiles that, caliber for caliber, were four times as heavy as to effective ranges two to three times as great; and they could do so with remarkably increased armor-penetration ability and accuracy.[10]

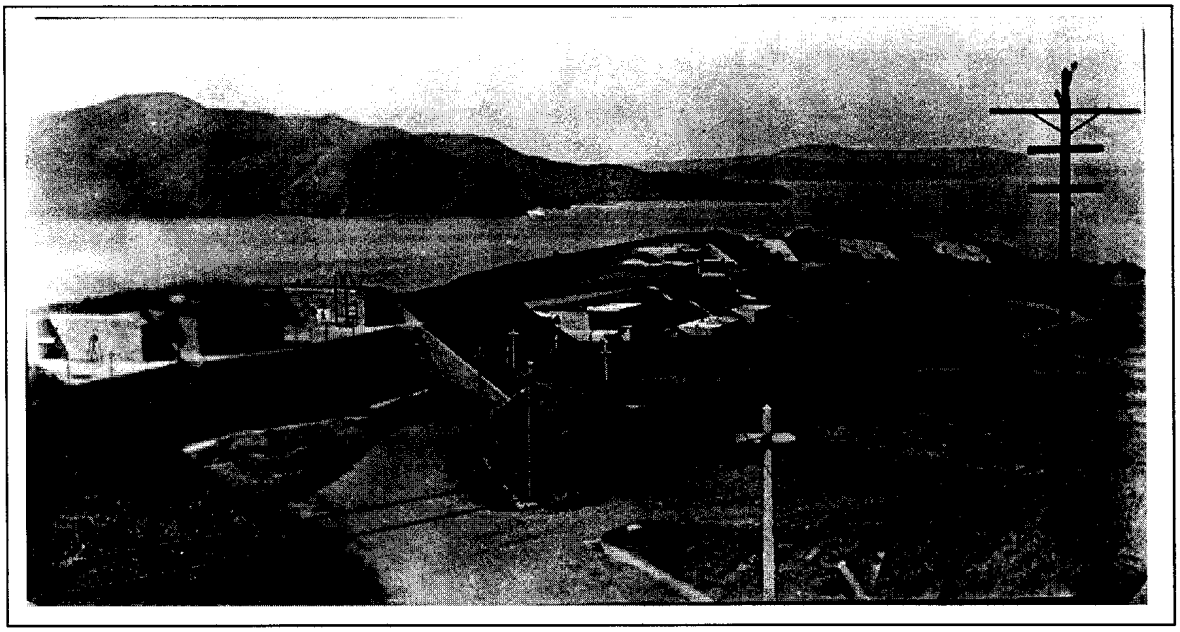
In 1885, Secretary of War William Endicott convened a long-overdue board to review the state of the American defenses and make recommendations for upgrading the nation's forts. Their recommendations became the basis for the next generation of construction that would extend from 1890 to 1910, and give rise to the designation "Endicott Era" for these works. In 1886 the Board made its report, calling for extensive new fortification projects at 26 coastal locales. Recommendations ran from gun batteries to mortars, to patrol boats and underwater minefields. Not all recommendations would be implemented, but the results would still bring sweeping changes to the coastal fortifications.[11]

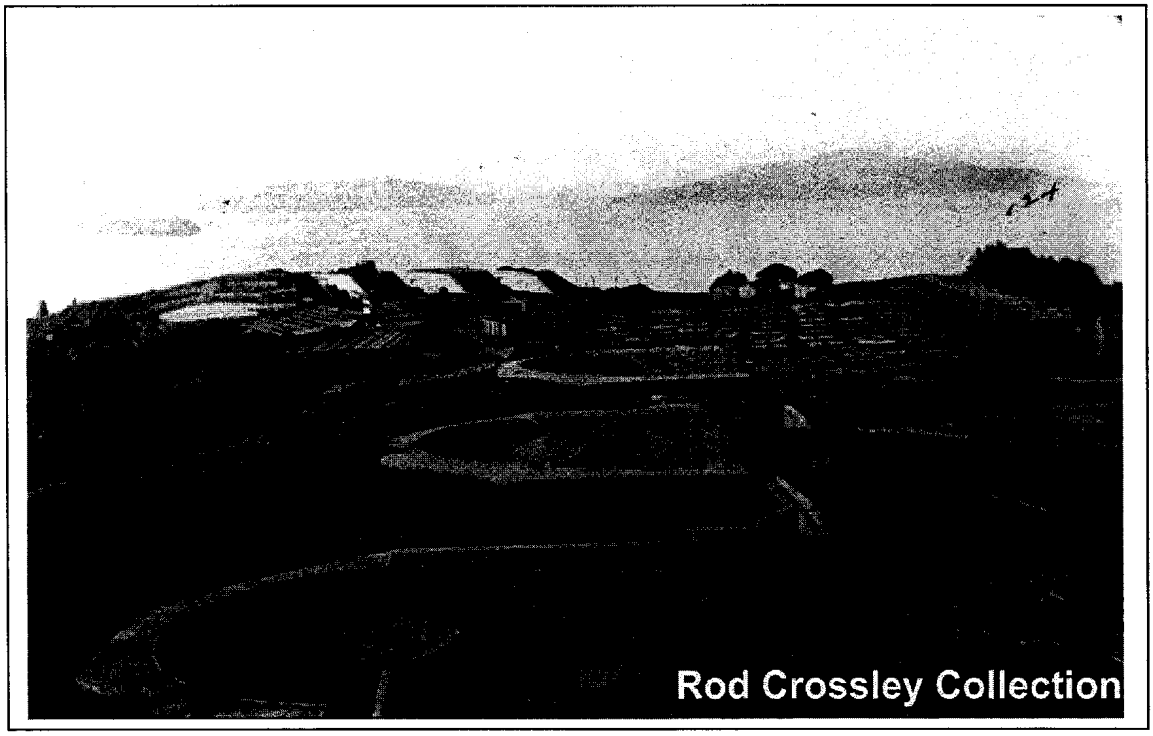
In general, the Endicott Board recommended emplacing several calibers of guns, each with its own anticipated targets, ranging in caliber from 12-inch rifles and mortars designed to deal with heavily-armored ships such as battleships and cruisers, down to 3-inch rapid-fire guns meant to take on swift motor torpedo and patrol boats. In between these extremes were several other calibers of guns, each with its own justification for existence, although it's hard to see what the tactical difference might have been between a 5.7-inch gun and a 6-inch gun. (Standardization would come later.) In addition, electrically controlled underwater minefields would be planted in shipping channels and approaches.

Beginning in 1890, Congress began acting on the Board's report and resumed making annual appropriations for construction of coastal defenses. In 1890 and 1891, it passed acts authorizing almost $2 million in new construction. San Francisco and New York Harbor were at the head of the list. Over the next several years, construction would proceed rapidly at these two ports that reflected their importance and the military's concern that they might be primary targets of enemy attack.[12]

Work began in 1890 above Fort Point, where ground was broken for a 10-inch disappearing gun emplacement in Battery Marcus Miller. Before long, additional batteries were being constructed at the post (formally named Fort Winfield Scott in 1882) that mounted a variety of large caliber guns, rapid-fire weapons and mortars. The best location for many of these emplacements was the bluff occupied by West Battery, and by 1900 five different Endicott batteries had been built atop its earthworks. These new works obliterated nearly every trace of the 1870s emplacements, but a handful of service magazines in truncated traverses survived to be incorporated into the new batteries.

The Endicott program would be succeeded by newer generations of coastal defense construction in the 20th century, but their stout emplacements would survive long after the guns were dismounted. In the Presidio, some of the 1890s emplacements would see military uses as late as the 1960s, frequently as storage facilities but sometimes as command posts and even soldiers' quarters during wartime.





***Figures 9 & 10**. Two views of Endicott batteries at Fort Scott along the former location of West Battery. (Above) From left to are Batteries Boutelle, Marcus Miller, Cranston and Lancaster. A portion of a trapezoidal 1870s traverse #21 is visible between Batteries Boutelle and Marcus Miller. (Below) A WWI cantonment area is visible beyond Battery Boutelle. (GOGA, PARC, Interp Coll)*

I. Construction

A. "Plan of 1870"

The construction of earthwork batteries at Fort Point followed very closely the guidelines set forth in the 1868 report by the Board of Engineers. The most extensive retelling of the construction of West Battery and East Battery is contained in the National Park Service publication *Historic Structure Report: Fort Point Historic Data Section*, prepared by historian Edwin C. Bearss of the NPS in 1973. This researcher has excerpted extensively the sections concerning West Battery taken from Bearss' landmark report. A copy of his HSR relating to the batteries' construction is included as an addendum to this report.[13]

Guided by the concepts contained in the Washington engineers' 1868 report on earthwork fortifications, the Board of Engineers for the Pacific Coast developed an extensive scheme of defense for San Francisco Bay. In their September 1870 report to the Chief of Engineers the members outlined their vision for works at Fort Point: "The best position on this shore for Barbette and Mortar Batteries to defend the approaches to the harbor were along the crest of the bluff, south of Fort Point, and that a powerful battery can be placed on the bluff East of the Fort."

The proposal was nothing if not expansive. In its original form, the Board envisioned West Battery as a series of gun and mortar positions to emplace 57 guns and 28 mortars, extending along the ridgeline from directly behind Fort Point all the way to Telegraph Hill in the Presidio (today's Robb Hill). Its guns would face almost due west and command the approaches to the Golden Gate. Guns on its extreme right flank could also intersect with fire from batteries planned at Lime Point.

East Battery, by comparison, was a relatively small work consisting of only 16 guns and four mortars. It was positioned so that its field of fire was almost entirely within the bay, half of its guns oriented towards Alcatraz Island and the others facing towards Point San Jose.

Following closely the Washington Board's guidelines, the traverses would be spaced 64 feet apart on their centerlines, allowing enough room for two 15-inch Rodman guns in each battery. This spacing would also allow sufficient room to allow for any modifications in platform design or carriages that the Washington Board might later require. (At this time the army was still considering the adoption of the King's Depressing Carriage described earlier.) Far behind the batteries, earthwork positions for riflemen would be constructed near Robb Hill to prevent the artillery emplacements from being seized from the rear.

But the Pacific Board was also realistic about the eventual expense, stating the batteries would "probably absorb in their construction al the appropriations that will be made for defensive works at Fort Point for several years." They prioritized work on various sections of the batteries, with initial priority going to the northern half of West Battery, which would include positions for a 20-inch Rodman, fourteen 15-inch Rodmans, and eight 13-inch mortars. (The proposed 20-inch gun would later be replaced by another 15-inch Rodman.)[14]

A meticulously detailed map was also prepared that accompanied the report, showing the locations of the proposed works. In later years this plan would be followed with almost slavish accuracy as actual construction work took place, and today's surviving features of West Battery only vary by inches from measurements shown on the 1870 proposal.[15]

The Chief of Engineers had to concur, of course, and went along with the Board's proposal, although he felt the West Battery positions, "though unnecessarily high and too oblique in direction for the most efficient fire on hostile fleets running through mid-channel to enter the Golden Gate," were found to occupy the only available ground in the area. The southernmost of its guns near Telegraph Hill would actually be more than 2½ miles from mid-channel – almost the extreme range of a 15-inch Rodman. Consequently, Humphreys only approved constructing the northern portion of West Battery – the portion that survives today. With these reservations, Humphreys sent the Fort Point

proposal to the Secretary of War, who approved the project on 9 November 1870, "subject to such changes in details by the Chief Engineer, as in the course of construction may be found advisable."[16]

Actual work on West Battery commenced in late December 1870, beginning with the six emplacements directly behind Fort Point. Initial projects included stockpiling of materials, building and improving roads to the construction site, grading of the battery site, and excavation and embankment of earth for its terreplein and traverse.

Over the next several months, battery construction proceeded swiftly at Fort Point indicating the army's desire to have modern fortifications completed as soon as possible. Extensive correspondence in the National Archives indicates that works began at the north end of West Battery and then proceeded in a southerly direction. By mid-April 1871 Stewart was able to report that work had progressed as far as the two mortar batteries, and that a portion of the traverse on the right flank of the battery had been embanked and excavations made for its magazine walls (today's magazine 21). By May, the front, side and end walls of the two mortar battery magazines had been raised to the spring lines of their arched interiors, and their parapets constructed.

Elsewhere along line of emplacements, work was in varying stages of progress on excavating, laying granite blocks and pouring concrete for gun platforms, constructing magazine walls, grading terrepleins, and sodding slopes. By 30 June 1871 the embankment of the terrepleins, traverses, etc. had been 2/3 completed for a length of 1,324 feet. Altogether 29,586 cubic yards of embankment had been positioned. Sodding totaled 7,180 yards. The breast-height wall had been begun, the masonry of two traverse magazines almost completed, and eight others about two-thirds finished. Foundations for 12 platforms and pintle blocks for mounting 15-inch Rodman guns had been put down. Altogether, 1,928 cubic yards of brick, stone and concrete work were in place.[17]

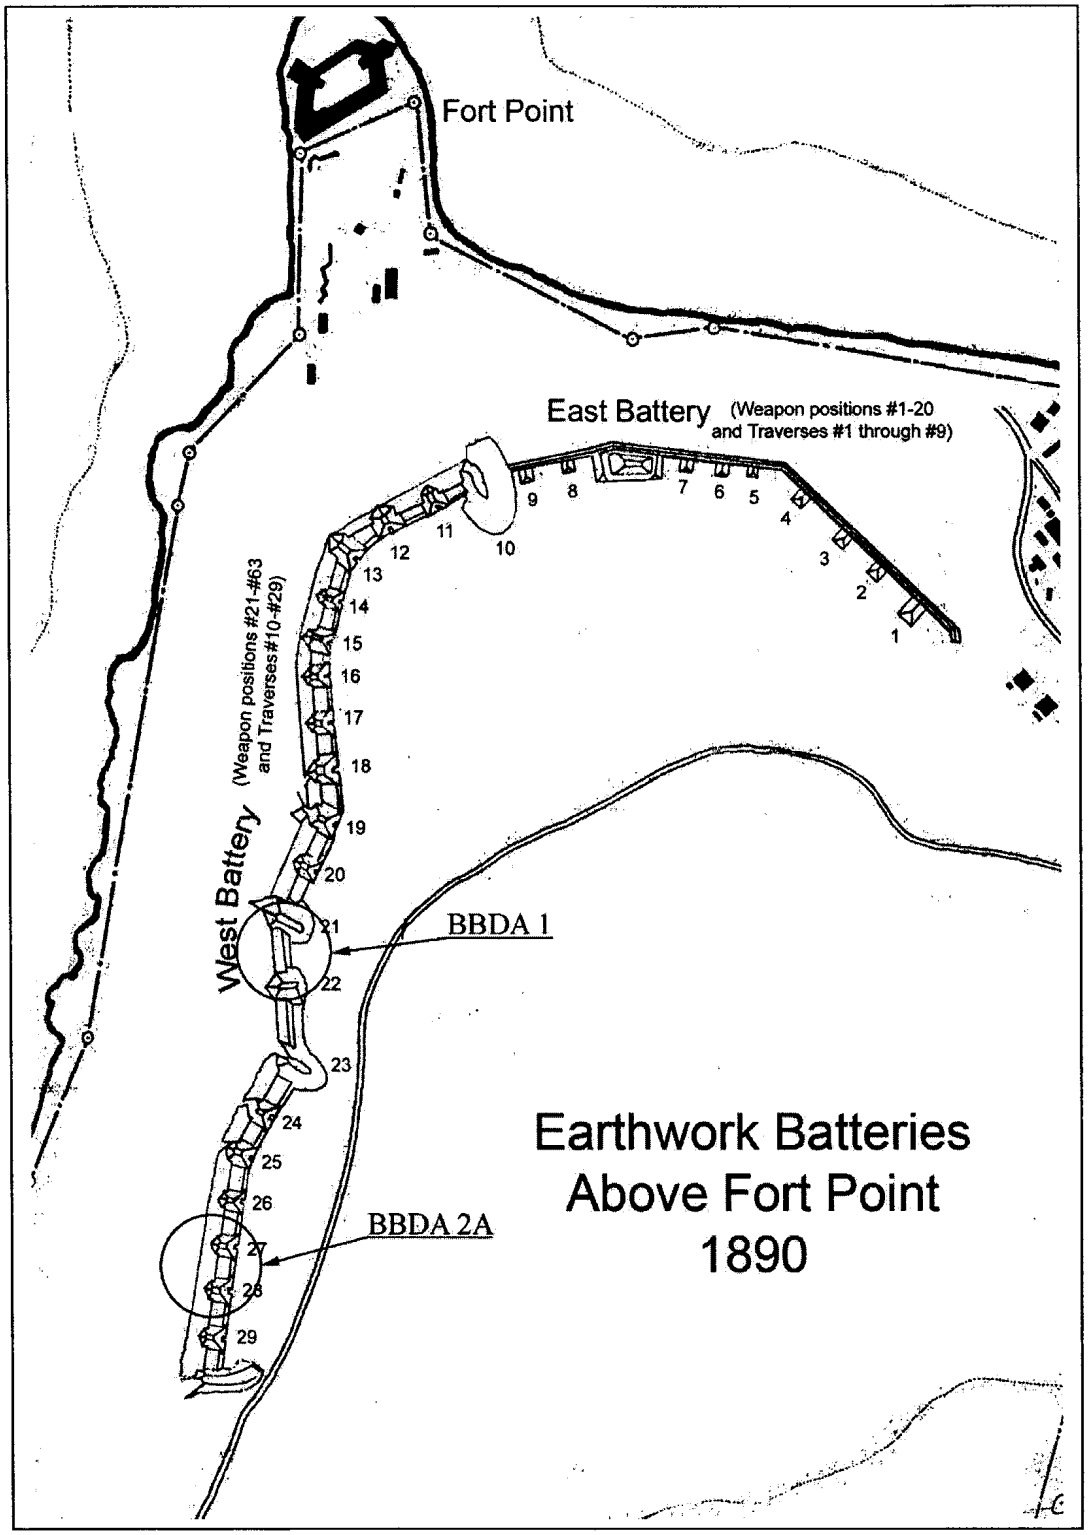


Figure 11. *Extent of completed earthwork batteries above Fort Point in 1890. Current Remedial Action project areas are circled.*

An unwelcome complication arose in early June when orders arrived from Washington directing that work on the batteries be suspended until decisions were made about how to arrange them to fit "King's counterpoise carriage."[18] This directive surprised the supervising engineer, Lt. Col. C. Seaforth Stewart, who had been proceeding with construction of standard barbette style emplacements, not depressing ones. He replied that the interior crests of the emplacements under construction at Fort Point varied in height from 180 to 196 feet above sea level, giving no tactical advantage to this style of embryonic disappearing gun.[19]

The situation was clarified in a couple of weeks when the Washington Board of Engineers made an updated report on the use of King's depressing carriage, and noted its inefficiency atop the Fort Point bluffs. "As it [West Battery] is quite exempt from enfilade fire and cannot be closely approached in front, it is believed that ordinary mounted barbette guns may be served with entire efficiency."[20] Work resumed in July.

Over the next year, work proceeded on the completion and partial arming of West Battery. Completing the magazines and emplacements occupied much of the workers' time, along with details such as sodding, grading, terracing, installing traverse rails, and hanging inner and outer magazine doors.[21] By summer 1872, Stewart was readying West Battery for its armament and noted that to complete the process he wished to finish the rear slopes and to 'unmask the fire' of several gun positions. This latter remark indicates that during construction, the terrain immediately in front of some of the guns had intentionally been left in its natural state, possibly to prevent prying eyes from seeing the work in progress. The cover now needed to be removed so the guns could have a field of fire.[22]

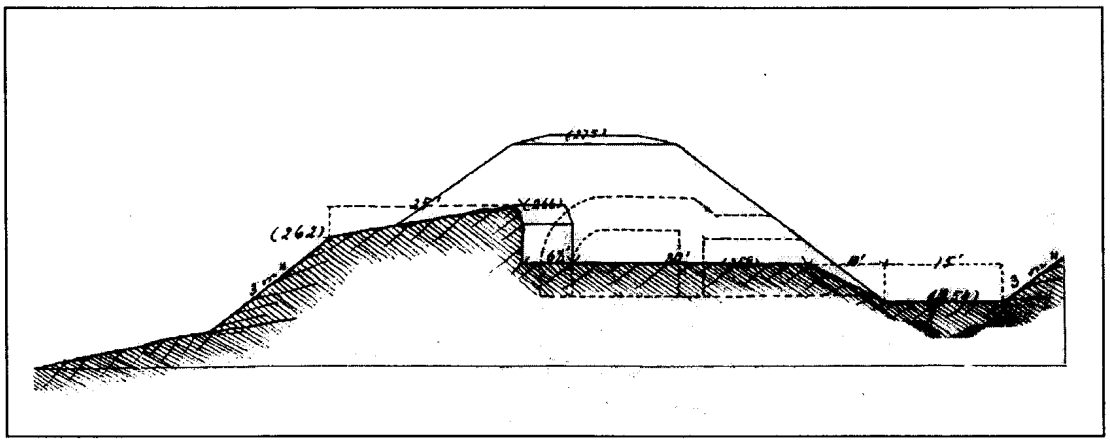

Figure 12. *Cross-section of a West Battery emplacement for Rodman guns. The traverse and its service magazine are also shown. (From the engineers' 1870 proposal for barbette batteries above Fort Point.)*

Plans for East Battery were finally approved in early 1873, and work commenced on that work shortly afterward. For the next year, work proceeded simultaneously on both East Battery and West. Although East Battery falls outside the immediate scope of this report, it should be noted that it differed from West Battery in one major feature: the presence of a covered way provided with a high earthen slope on the backside of the emplacement (a *parados*) that protected the road and battery from enfilade fire.

At East Battery, the engineers were given permission to elevate each pair of guns slightly from the adjacent pair. As the emplacements changed in elevation, they would "become better protected" from warships outside the Golden Gate, using the sloping topography of the hill west of the emplacements to form a parados.[23] The layout of Battery East and its sunken road – later buried – were documented in a 1934 aerial photograph showing early construction work on the Golden Gate Bridge. (See Figure 13.)[24]

Figure 13. *Aerial view of East Battery before construction of the Golden Gate Bridge toll plaza, showing the covered way and parados behind the emplacements. Battery Lancaster is at lower right. (Courtesy GG Bridge, Hwy & Trans. Dist.)*

By contrast, West Battery did not have a covered way. While some – but not all – of its emplacements did have reverse slopes, these features varied in height from two feet to slightly more than ten. None formed a true parados, but could better be described as uneven road shoulders resulting from the undulating topography adjacent to the emplacements.

Numbers for the individual emplacements became standardized during construction of the two batteries. It should be noted that the terms West Battery and East Battery were never formally designated military names but evolved out of common usage. To the army's constructing engineers, the fortification was simply one large earthwork. Correspondingly, they began numbering the emplacements at the extreme right flank of East Battery and numbered consecutively from east to west.

In its final form, East Battery consisted of twenty gun positions numbered #1 through #20 (including platforms for four mortars), and West Battery consisted of forty-three positions numbered # 21 through #63 (including platforms for eight mortars).

For reference, Remedial Action Area BBDA 1 is located on the site of historic mortar emplacements #42-#45, while the road portion of Remedial Action Area BBDA 2A is on the site of historic Rodman positions #58 and #59.

Col. Stewart reported that West Battery was "essentially completed" on 30 June 1873. The magazines could all be used (although not all the asphaltic floors had been laid); stone platforms, pintles and traverse rails had been completed for twelve Rodmans; a ramp had been constructed between West Battery and East Battery; and eight wooden platforms for 13-inch mortars had been constructed in the two mortar emplacements located midway along the line of batteries. In his annual report, Stewart noted that twelve 15-inch Rodmans had been emplaced, all of them in positions on the right flank of West Battery.[25]

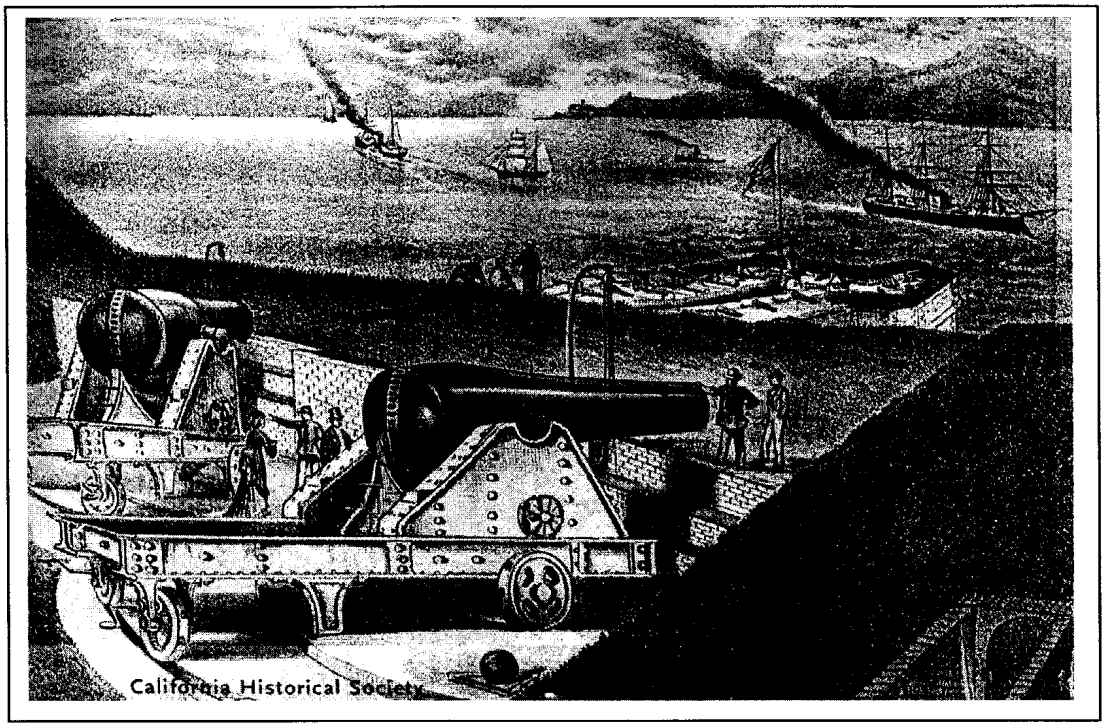

Figure 14. *A pair of 15-inch Rodmans in West Battery as portrayed in an 1877 issue of "The Wasp," a satirical San Francisco publication. The accompanying article berated the U.S. Government for wasting money on constructing obsolete fortifications. The artist took several liberties with perspective and location, since Fort Point is not visible at this angle from West Battery. Also, the fort is drawn backwards. (California Historical Society)*

On 18 May 1874, the Rodmans in positions #21 through #32 were test fired for the first time. The targets were located at distances of from one to two and three-quarter miles distance, and the guns loaded with powder charges ranging from 60 lbs. to 100 lbs. When fired at elevations of 33 degrees the Rodmans and carriages performed perfectly, but when one 15-incher was intentionally fired at 0 degrees elevation it recoiled violently against the end stops on its carriage. Although the iron chassis and carriage were slightly damaged, the emplacement itself took the shocks well and suffered only slight spalling of granite on the pintle block. The earthworks hadn't fared quite as well, though, and it was reported that the muzzle blast from the horizontal firing experiment had torn the sodding off the parapet.[26]

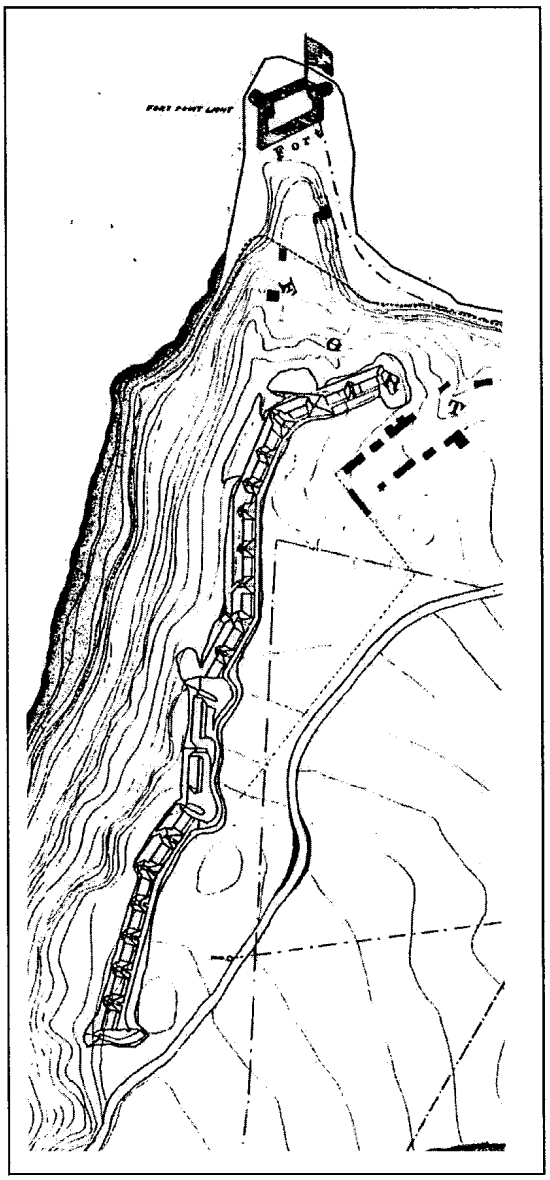

Figure 15. *West Battery in 1880. (GOGA, PARC)*

When Congress decided in Fiscal Year 1876 to reduce funding for harbor defenses, Fort Point was hit hard. Instead of the $80,000 requested, only $25,000 was allocated.[27] The result was an immediate changeover from construction to mere maintenance. Work was suspended on both batteries, and before even a single gun was ever emplaced in East Battery. The scene was grim for the supervising engineer, and would only get more frustrating. Historian Bearss summarized the sad entries from the annual reports for the following years:

"Congress for the next 14 years refused to vote funds for

construction of seacoast fortifications, thus preventing completion of Battery East. With work suspended, the earthen batteries slowly deteriorated. Weasels and gophers burrowed into the traverses and parapets, and torrential rains caused some of the magazines to leak, with serious erosion wherever the works had not been sodded."[28]

Eventually, civilian "fort keepers" were employed with the paltry maintenance funds allocated the army, whose jobs included security, mowing earthworks, scraping rust, and painting ironwork. Sometimes they were assisted by soldiers from the regular garrisons of old Fort Point – that is, when the fort was occupied. One 1880s report stated that portions of the sodded slopes of the earthwork parapets and traverses had recently been mowed, and observed how the sod consisted of "the thin and now matted roots of weeds and grasses," and without additional labor and expense for watering and weeding, it was impossible to keep the slopes "looking well during the long dry season."

Experience had shown the sod actually held up better *not* being mown when exposed to "the sun and strong steady winds of summer," and that the weeds and grasses acted as a mat, keeping the "light, dry soil, loosened and pulverized by the burrows of gophers . . . from being blown away." For this reason, considerable areas of the slopes were left unmowed.

Given the lack of funds for nearly five years, and all the hindrances to carrying out proper maintenance, Col. Stewart took a remarkably positive outlook when he reported the batteries looked "in tolerable good order."[29]

Periodically, the watchmen and the garrison were also able to perform maintenance on the non-earthwork portions of the batteries. These actions included clearing drains, painting doors, and painting and lacquering the ironwork on the wooden mortar platforms.

An 1882 inspection of the earthworks reported a variety of completed and incomplete emplacements. It also contained the notation that 12 timber platforms for heavy mortars

had been laid in West and East Batteries, but that decay had set in. It also noted that ground had been prepared at the south end of West Battery for 14 Rodman positions but no platforms had ever been constructed there.[30]

For some unknown reason, a test firing of the long-neglected 15-inch guns took place on 1 October 1884. The guns were manned and the targets selected: an offshore rock about halfway between Fort Scott and the Cliff House. After a couple of firings with reduced charges and only so-so accuracy (blamed on defective fuses), the colonel in charge ordered a gun loaded with a 450 lb. solid shot and a full charge of 100 pounds of black powder. The results were predictable. The aging weapon recoiled along its chassis, which in turn buckled under the strain, allowing the 50,000 pound barrel and top carriage to jump completely off the chassis. The barrel dismounted itself and ended up splayed across the battery.[31]

In 1886, maintenance work ceased entirely for two years when Congress stopped all appropriations for preservation and protection of fortifications. When funds became available once again in 1888, workers cut brush and weeds around the earthworks, repaired sodding on slopes and broken ventilators, cleaned brickwork, painted magazine doors, and built steps over the earthen parapets. Iron plates from ten of the badly decayed mortar platforms were removed and stored in adjacent magazines.[32]

B. "Endicott Era" Construction

West Battery was perfectly sited to deal with an enemy approaching the Golden Gate, and for this strategic reason it was also selected as the site of the first Endicott batteries to be constructed in the San Francisco defenses. Work began on the new fortifications in June 1891 under the direction of Col. George Mendell of the Corps of Engineers.

By the end of the first month, Mendell's workers had dismounted four of the 15-inch guns in West Battery and begun demolishing their masonry platforms and other nearby emplacements. With the ordnance and earthworks gone, work next commenced on excavations for the disappearing gun emplacements. Progress was rapid, and by December 1892 six of the new Endicott emplacements were nearly completed except for their armament. (These emplacements today comprise Batteries Marcus Miller and Godfrey.)[33]

Construction on another concrete emplacement in October 1896 required the removal of four more 15-inch Rodmans and their earthwork emplacements. (The site of today's Battery Lancaster position #3.) The guns were dismounted, their carriages and platforms salvaged, and the traverses and earthworks demolished.[34]

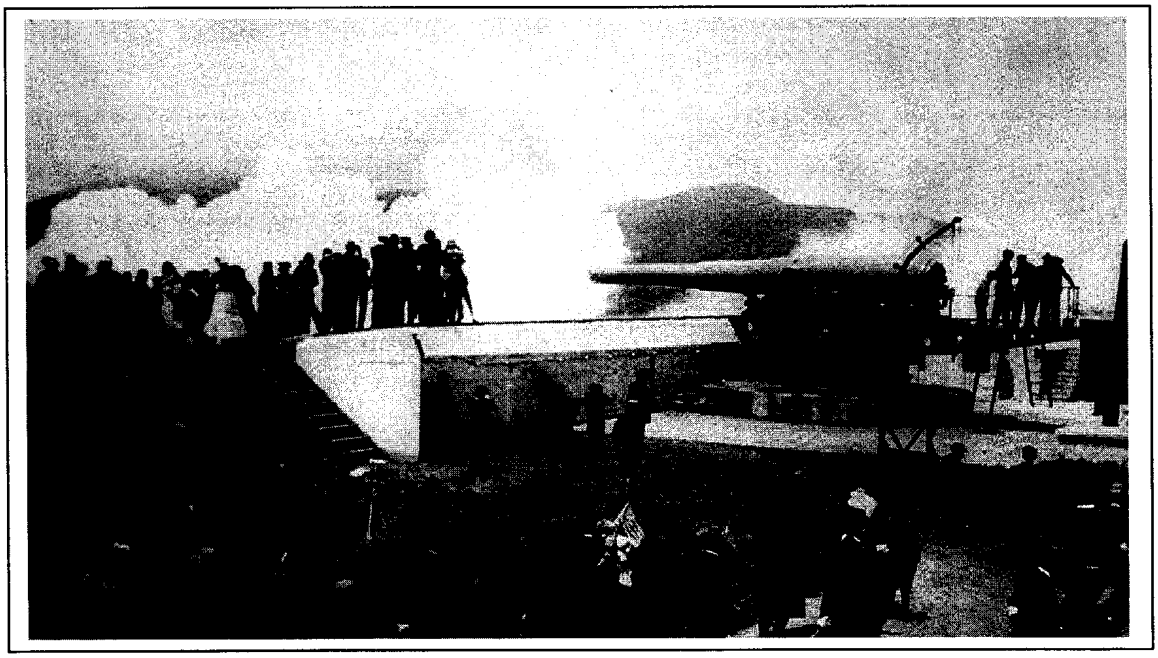

Figure 16. *A 12-inch rifle in Battery Godfrey at the moment of firing, c1915. The brick entrance to Traverse #27, integrated into Godfrey's earthworks, is visible at lower left. (GOGA, PARC)*

Then in June 1897, work began on two more emplacements (today's Battery Cranston) that necessitated removal of two more Rodmans, their carriages and platforms from West Battery. These were subsequently removed and their positions demolished. Only five 15-inch Rodmans remained in place: four in the extreme right end West Battery and one in

East Battery. (The latter weapon – East's first armament – had only recently been emplaced after being dismounted from West Battery.)[35]

Work began in summer 1898 on the last concrete emplacements that would require the removal of the armament from West Battery. These two disappearing gun positions (today's Lancaster #1 and #2) stood directly on the site of Rodman positions #21-24, and by the end of the year these last four smoothbore weapons had been removed to make way for new construction. With their removal, West Battery effectively ceased to exist.[36]

Battery East, although initially planned as the site for five more Endicott weapons, was left undisturbed. Although it had never been completed during the original "Plan of 1870" construction, it now mounted five weapons: a 15-inch Rodman in position #16 and four 8-inch converted Rodman rifles in positions #13, 14, 17 and 18.

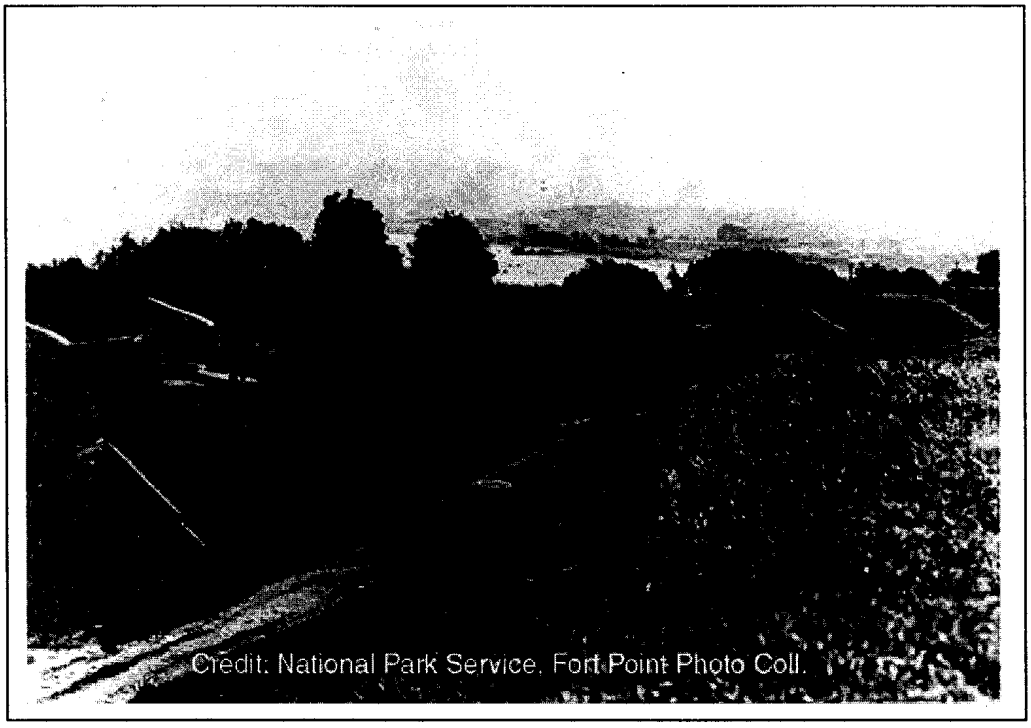

Figure 17. *A pair of 8-inch rifled Rodmans and the covered way behind East Battery, 1915. The buildings of the Panama Pacific International Exposition can be seen in the distance. (GOGA, FOPO Coll)*

The last Endicott fortification constructed at West Battery was Battery Boutelle, an emplacement for three 5-inch guns on balanced pillar mounts. No armament had to be removed to make way for the new work, since the 13-inch mortars intended for the site had never been mounted. Even their wooden platforms had been removed sometime prior to 1898.[37] When designing Boutelle, the engineers took advantage of pre-existing earthworks on the site by nestling the new emplacements snugly between traverses #22 and #23. Work on the battery began in 1898 and was completed in 1901. During the course of construction, the decision was made to retain the magazine in Traverse #22 and incorporate it into the new battery, where it apparently served as an auxiliary ammunition storage room for the battery's 5-inch fixed ammunition under the designation "old magazine."[38]

Retelling all the details of construction of the Endicott batteries falls outside the scope of this report, but the following summary provides an outline of their origins. Starting at the north end of the line and working south, they are:

Name	*Armament*	*Commenced*	*Completed*
Battery Lancaster	Three 12-inch rifles on disappearing carriages	1896	1900
Battery Cranston	Two 10-inch rifles on disappearing carriages	1897	1898
Battery Marcus Miller	Three 10-inch rifles on disappearing carriages	1891	1898
Battery Boutelle	Three 5-inch rifles on Balanced Pillar mounts	1898	1901

Battery Godfrey	Three 12-inch rifles on barbette mounts	1892	1896

II. Alterations and Later Uses

Following its disarming, only a few traces of Battery West remained. These included six traverses and magazines (#s 21, 22, 23, 27, 28 and 29), a four gun mortar pit (positions #s 42-45), and the partial outlines of two unfinished two-gun Rodman emplacements at the south end of the line (positions #s 60-63). One of these magazines (#23) was physically incorporated into the structure of Battery Godfrey and became a store room off the battery's generator room. The other surviving magazines remained as distinct structures with their own entrances, and show up on period maps and drawings simply labeled "magazine." The rooms' exact uses are unknown, but they probably served as simple storage spaces for the adjacent Endicott batteries.

The history of the Endicott batteries surrounding the Golden Gate is documented extensively in historian Erwin Thompson's *Historic Resource Study: Seacoast Fortifications of San Francisco Harbor*, prepared for the National Park Service in May 1979. For the batteries along the former alignment of West Battery, their history was relatively short. By 1918 the batteries were recognized to have several faults: all were located too far inside the Golden Gate straits to have effective fields of fire; their carriage designs prohibited the barrels from being elevated for maximum range; and they were of an obsolescent design. Within a few years of their completion, the batteries' defensive roles were replaced by forts that had better fields of fire and were located further to the west – and closer to any potential enemy – posts such as Fort Miley in San Francisco and Fort Barry in Marin County.

Battery Boutelle was the first to be disarmed in 1918 when its 5-inch guns were removed for field use in Europe. Battery Cranston was disarmed that same year, and Marcus Miller's guns were removed in 1920. Cranston and Godfrey both retained their guns through World War II, but apparently more as a matter of neglect than for any tactical purposes. They finally lost their armament in 1943 during a general scrapping of 10-inch and 12-inch Endicott weapons remaining in the Bay's defenses.

A. Alterations to 1870s Traverses

The earthen traverses covering these magazines also survived, but four of the six were truncated by several feet to lower their profiles when viewed from the sea. When originally constructing the earthworks, the engineers seemingly gave little thought to making West Battery inconspicuous. Historic photographs taken from the bay reveal that the battery's traverses stood out against the sky as a series of tall, trapezoidal shaped mounds stair-stepped along the Fort Point hillside. The battery was so pronounced that its earthworks and guns were even visible from Pacific Heights. (See illustrations following.)

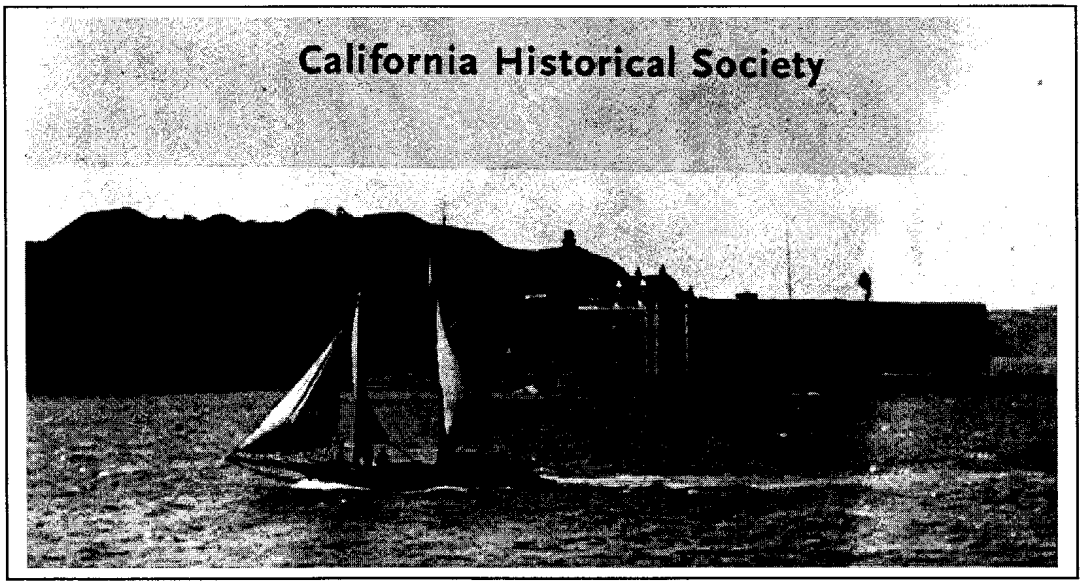

Figure 18. *Fort Point and a portion of West Battery as viewed from the bay, c1890. Note the 15-inch Rodmans mounted between the traverses. (California Historical Society)*

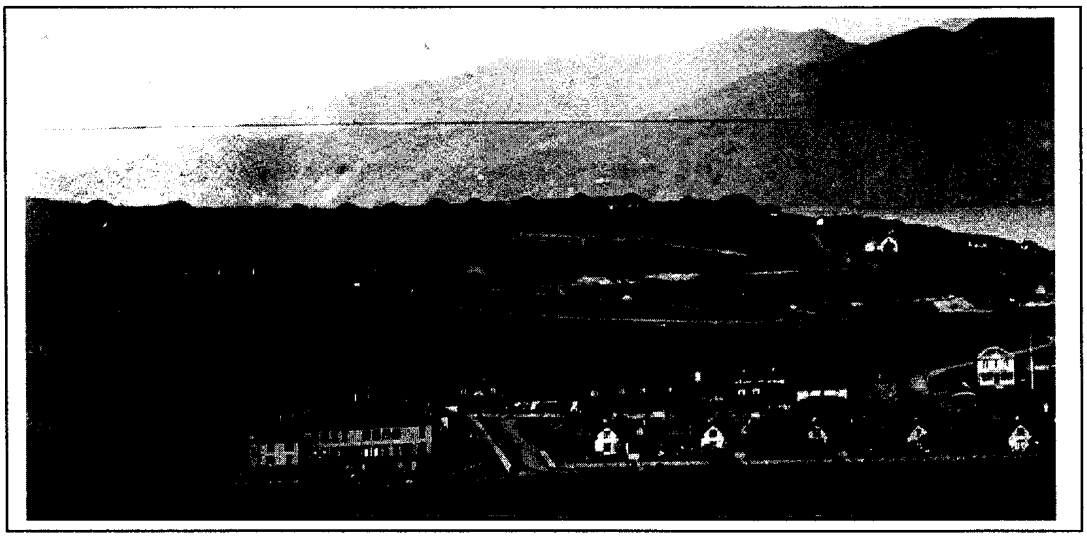

Figure 19. *The traverses of West Battery appeared like a serrated edge in this view from Broadway and Lyon Streets in Pacific Heights. A portion of the Presidio's main post is in the foreground. (California Historical Society)*

By contrast, the army wanted to draw as little attention as possible to the presence of the Endicott batteries, not so much for secrecy but rather to deny enemy gunners a good target. The traverses from the 1870s that still remained adjacent to the newer works would have only served to draw attention to the fortifications' locations.

In his 1920 treatise *Notes on Seacoast Fortification Construction*, Colonel Eben E. Winslow of the U.S. Army's Corps of Engineers described the evolving theory of coastal fortification design in the late 19th century:

> In the earthen emplacements constructed during and just after the Civil War, the guns were mounted on barbette carriages and were, therefore, always visible. In order to obtain a sufficient volume of fire they were mounted fairly close together along a parapet, although it was customary, wherever infilade [sic] fire was feared, to place frequent traverses in the line of guns so as to reduce the effect of this enfilade fire. In general, the guns were emplaced in pairs, two guns in the interval between two traverses.

> These traverses extended high above the parapet and, in fact, above the guns and, therefore, were visible from a considerable distance. The guns then in use were mounted in barbette and were always exposed to view, the ranges used at the time were comparatively short, and since the guns themselves were not concealed no concealment was lost by the exposure of the traverses to view.
>
> When, however, the disappearing [gun] principle was introduced into seacoast gun carriages so that the gun in the loading position was entirely out of sight, it became desirable to conceal, if possible, the position of the gun. It appeared to be desirable to reduce the height of the traverse to that of the parapet, so that when seen from the front, the emplacement appeared with an unbroken horizontal crest, no guns being visible and no traverses indicating the approximate positions of the guns. The early designs for disappearing emplacements as prepared by the Board of Engineers were all based on this idea.[39]

During the construction of the Endicott batteries, the tall earthwork traverses of West Battery were reduced in height to correspond to the adjacent parapets and superior slopes of the new concrete fortifications. Although the engineers' reports for the concrete fortifications at Fort Scott make no specific reference to lowering the old traverses, it was likely done in accordance with the new design standard described by Winslow as "an unbroken horizontal crest … and no traverses indicating the approximate locations of the guns."

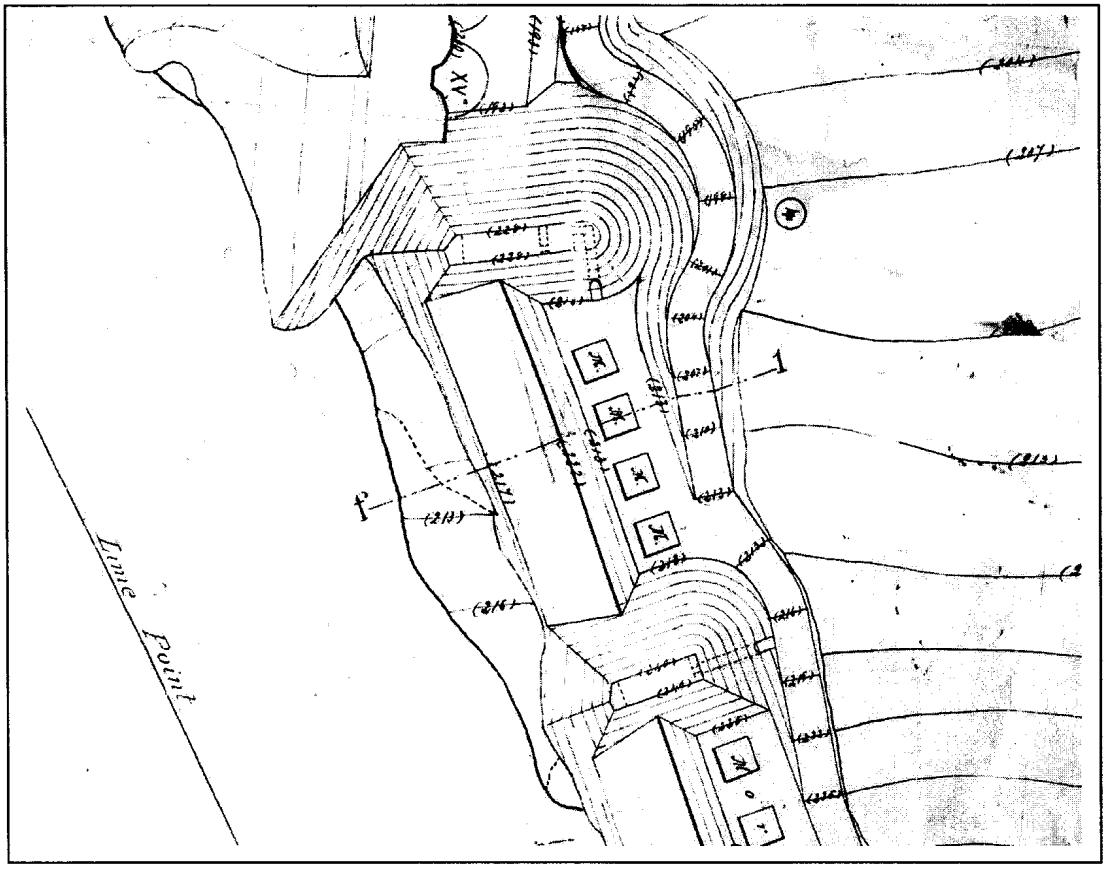

Figure 20. *Section of original 1870 engineer plan showing Traverses 21 (top) and 22 (bottom) and positions for 13-inch mortars. This is remedial project area BBDA 1. (NARA RG77, Drawer 94, Sheet 102)*

The best-documented example of reducing a traverse's profile is Traverse #21 on the right flank of the mortar battery and adjacent to Battery Marcus Miller. The original 1870 map shows a proposed crest of 228 feet for this traverse, while an 1891 drawing shows the finished elevation as 229 feet. (Discrepancies of about a foot are common to historic maps of the area.) By 1902, however, seven feet of the traverse had been shaved off and its elevation reduced to 222 feet, bringing its crest to the same level as the superior crest of the adjacent mortar emplacement. Although this left the magazine with only about two feet of earthen cover, the traverse was now much less conspicuous. Viewed from the water, the battery now appeared more like a simple earthen bank in the hill.[40]

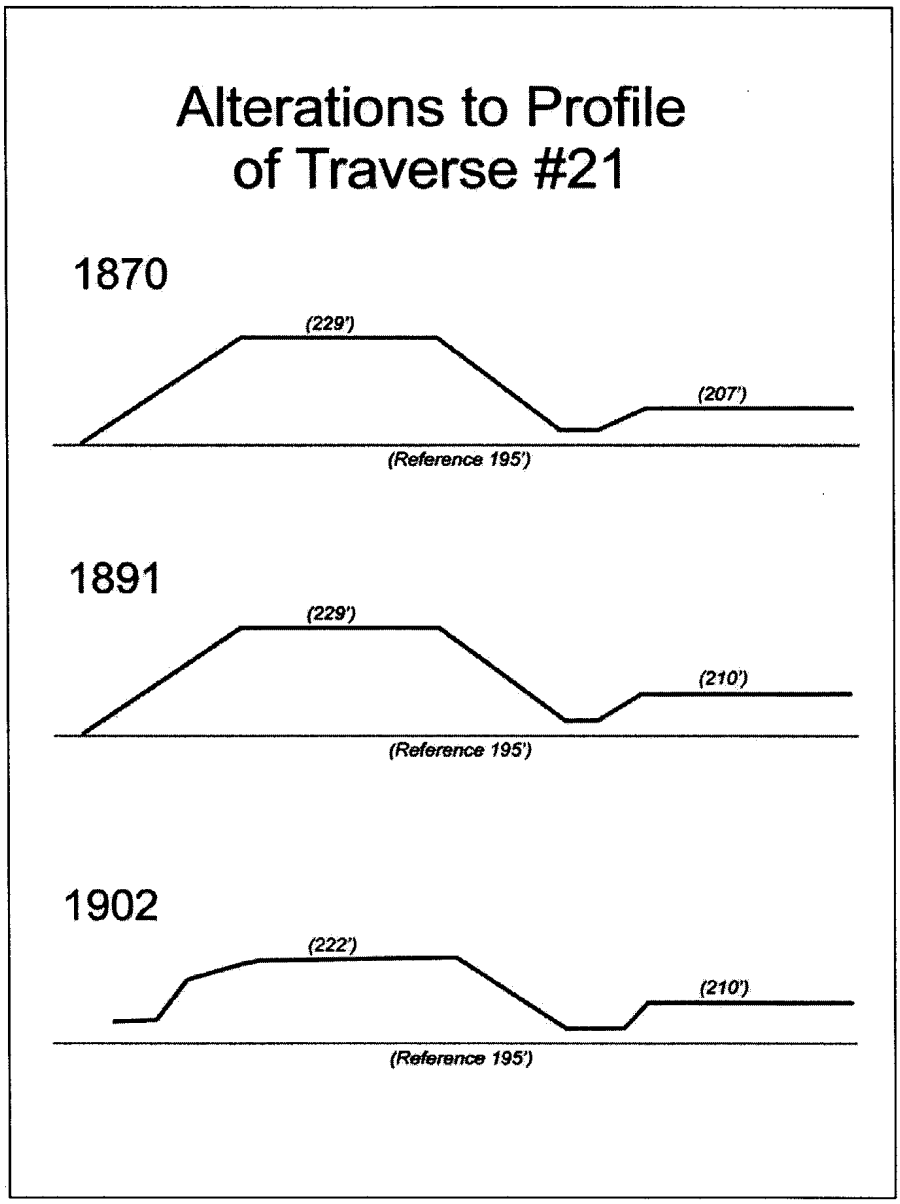

Figure 21. *Three views of Traverse 21, view north. Note also the change in road width and the three-foot height increase of the open area behind the battery.*

The same re-contouring efforts occurred at Traverse #27 on the left flank of Battery Godfrey, which was reduced in height from an original elevation of 274 feet to a post-Endicott elevation of approximately 270 feet.[41] Based on visual inspections, similar reductions in height appear also to have taken place at Traverses #28 & 29. (Confirming measurements have not yet been made.)

By contrast, Traverses #22 and #23 seem to have retained their original contours, although their crests are now suffering from erosion caused by visitors scrambling across the batteries. In fact, the footprint of Traverse #22 is somewhat larger than when first constructed, probably due to additional fill being placed around its eastern and southern sides when Battery Boutelle was constructed. As a result of this additional fill, a 25-foot extension had to be added to the corridor leading to the traverse magazine inside.[42]

B. Alterations to 1870s Gun Emplacements

Mortar Battery. The four mortar positions located between Batteries Marcus Miller and Boutelle lasted well into the 20th century, along with the traverses flanking both sides of their emplacement. Subsequent alterations and filling can be traced through historic drawings made of the battery, beginning with a section from the original 1870 engineer map for the Fort Point batteries. This map shows the relationship between the original slopes, the mortar platforms, road, reverse slope, and "natural surface." (See Figure 22.)

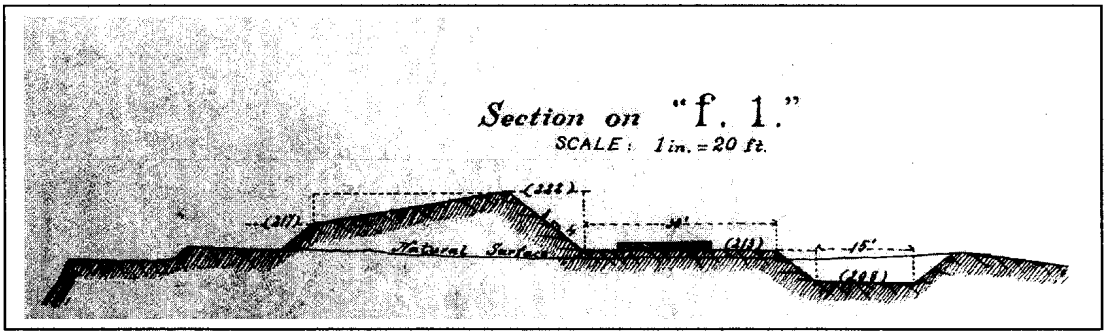

Figure 22. *Section "f, 1" through mortar positions, showing original height of road cut behind emplacement. (NARA RG77, Drawer 94, Sheet 102)*

A map prepared in 1902 showing a proposed (but never implemented) extension of the Endicott batteries onto the mortar site revealed that the original outline of the earthwork emplacement was still recognizable, complete with the interior slope and intact (albeit truncated) earthen traverse and magazine #21 on the right flank. The four wooden platforms were gone, but the open area where they had been located was still plainly discernible.[43]

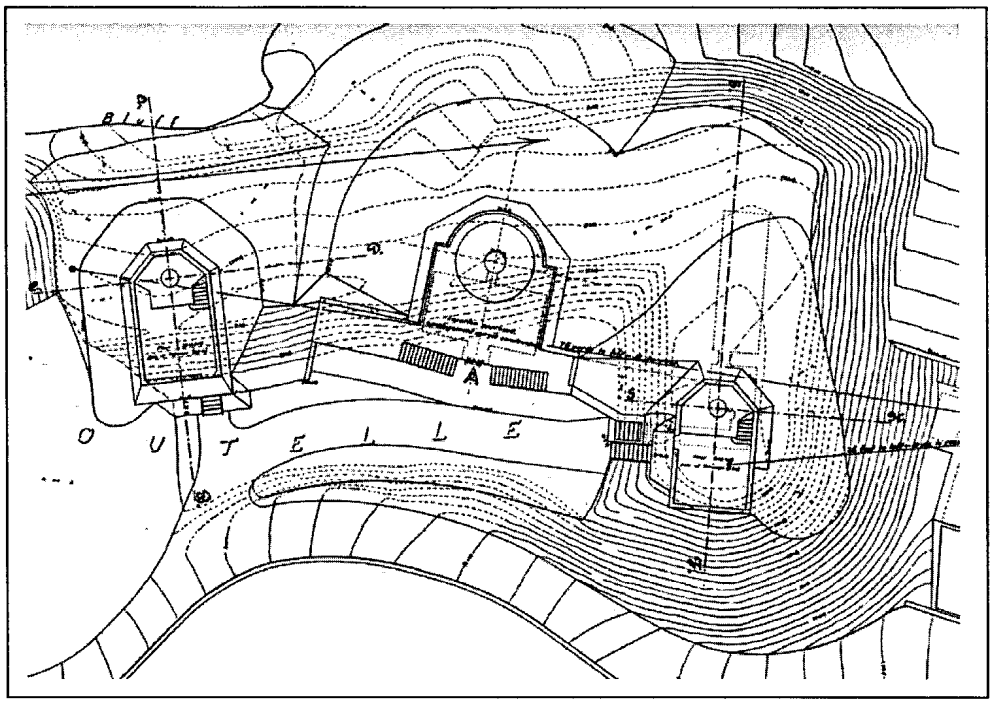

Figure 23. *The outlines of Traverse 21, its magazine, and the former mortar battery location are visible as dotted lines in this 1902 proposal for an extension of Boutelle. This remedial site BBDA 1. (PARC, GOGA)*

At some undetermined date, the superior slope of the old mortar battery was flattened and a disposal site established on its site. This dump was likely associated either with the garrison buildings at nearby Fort Winfield Scott or with a sprawling complex of World War I temporary barracks erected behind the batteries in 1917. Initially, debris appears to have been simply dumped down the face of the cliff leading to Baker Beach. In 1922, a concrete and brick trash incinerator was built on the flattened area. Designated as Fort Scott Building #237, it measured 6'4" x 8'and cost $414 to construct. It was arranged on a general east-west alignment across the former superior slope.

In 1934, the original incinerator was replaced by a newer version built primarily of concrete. It measured 9' x 13' and cost $800. Based on historic photos, this new incinerator was located on the north side of the dump area, and was oriented on a roughly north-south alignment. To make room for this structure, yet another portion of the 1870s superior slope had to be cut away. The 1934 photograph also shows what appears to be a flat paved area directly in front of the incinerator possibly made of poured concrete that

allowed vehicles to pull directly up to the furnace doors. Unfortunately, the extent and exact composition of this paving feature is not known. (See figure 25.)

Figure 24. *1922 incinerator on dump site. View looking south. Remedial site BBDA 1 (GOGA, PARC)*

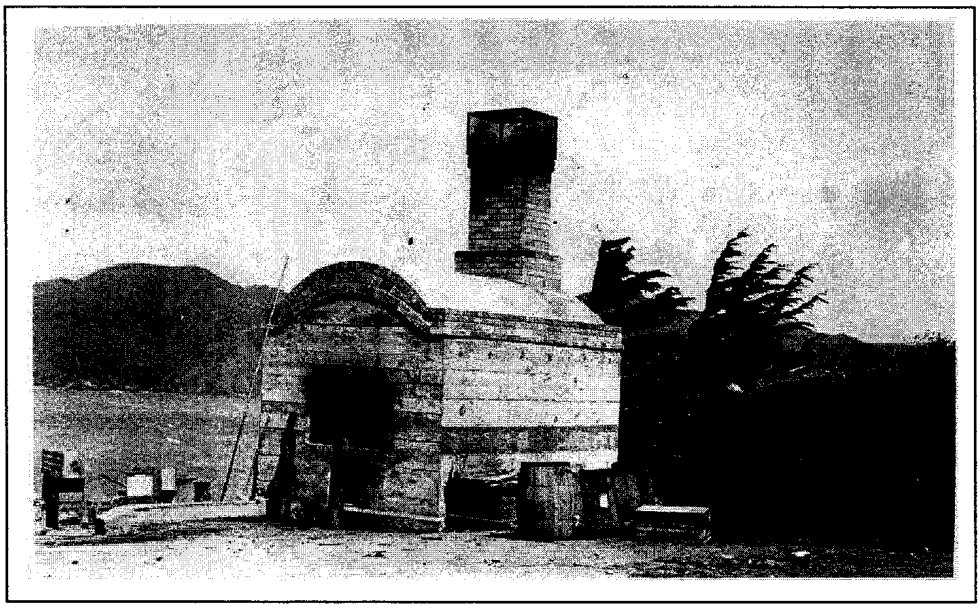

Figure 25. *1934 incinerator. View north. Note excavation into earthworks at right. Remedial site BBDA 1. (GOGA, PARC)*

Photographs in the collection of the Golden Gate Bridge District show that dumping activities continued at the site at least through 1967. In that year, a large expansion of the disposal site was recorded. (See GG Bridge photo May 1967) This material in the photo covers not only the slope below the dump site but also fills the flattened dump area on the former superior slope of the mortar battery.[44]

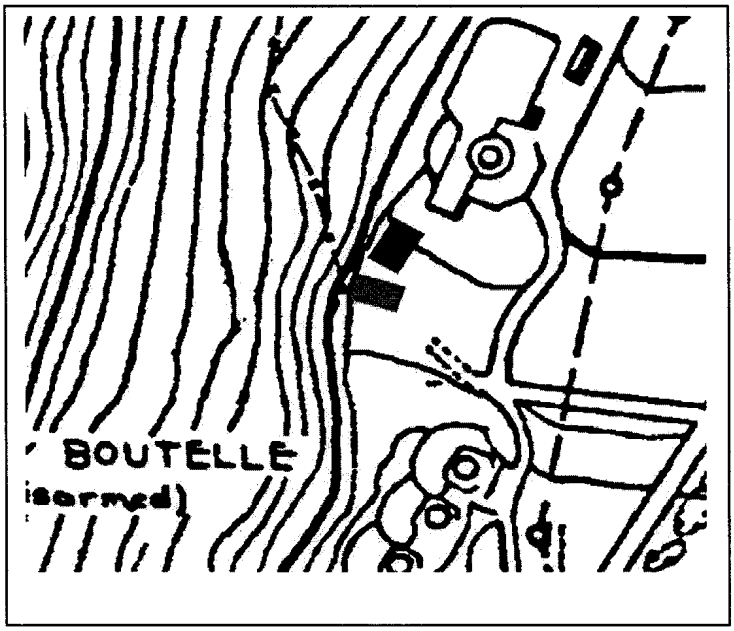

Figure 26. *Approximate locations of two incinerators: 1922 (lower) and 1934 (upper)*

Figure 27. *The 'new' incinerator at the dump site, lower right. February 1935. (Courtesy GG Bridge, Hwy & Trans. Dist.)*

Figure 28. *An aerial photo taken in May 1967 documents extensive fill on the former site of both the dump and across the road behind the batteries. A pond of water has apparently formed directly over the dump site. The curved outlines of the traverses flanking the former battery are still visible. Remedial site BBDA 1. (Courtesy GG Bridge, Hwy & Trans. Dist.)*

Rodman Emplacements. As noted in the 1882 inspection of West Battery, the last fourteen Rodman positions were never completed. An 1898 plan of the Fort Point batteries confirms that construction work on the positions had only extended to completion of the magazines and traverses, and grading of the parapets, superior slopes and glacis. No work was ever carried out on the masonry of the parapet walls lining the interior slopes, the firing steps, or gun platforms. The 1898 plan also reveals that a never-constructed traverse and magazine were planned for the south end of the line, and would have become traverse #30.[45] Where or not any grading for this traverse had been completed is unclear. (The same map showed that three of the wooden platforms had been removed from the mortar battery between traverses #21 and #22, and that a fourth remained in place but was "unserviceable.")

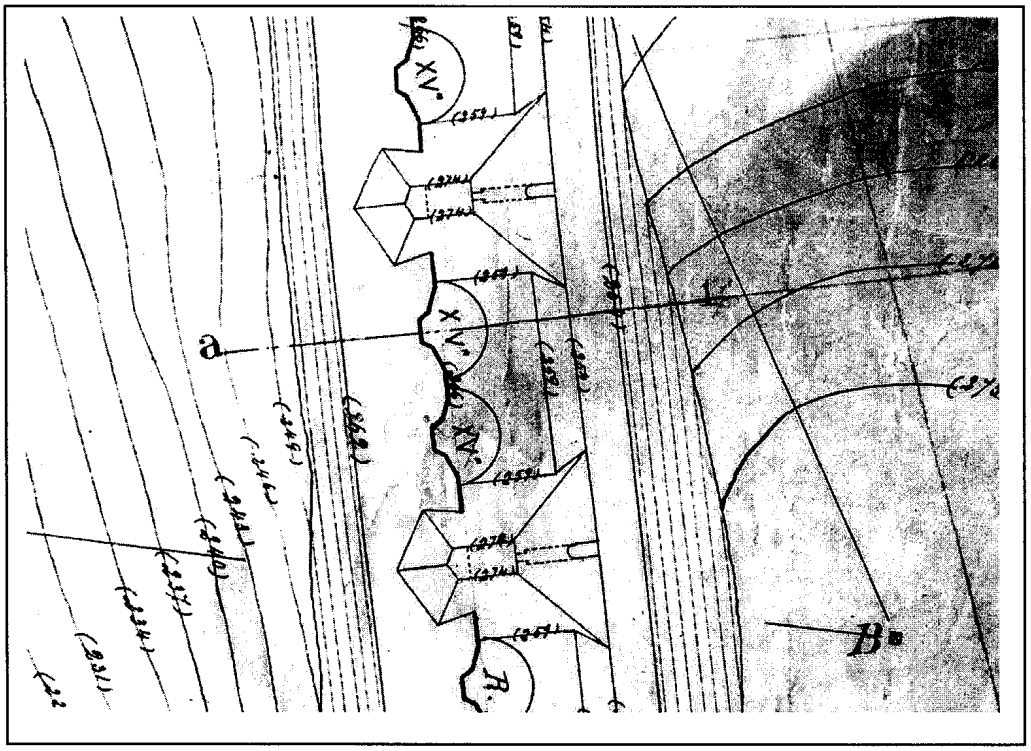

Figure 29. *Section of original 1870 engineer plan showing Traverses 27 (top) and 28 (bottom), and Rodman positions #59 and #60. Section a – 1 is the site of the present overlook access road. This is remedial project area BBDA 2A. (NARA RG77, Drawer 94, Sheet 102)*

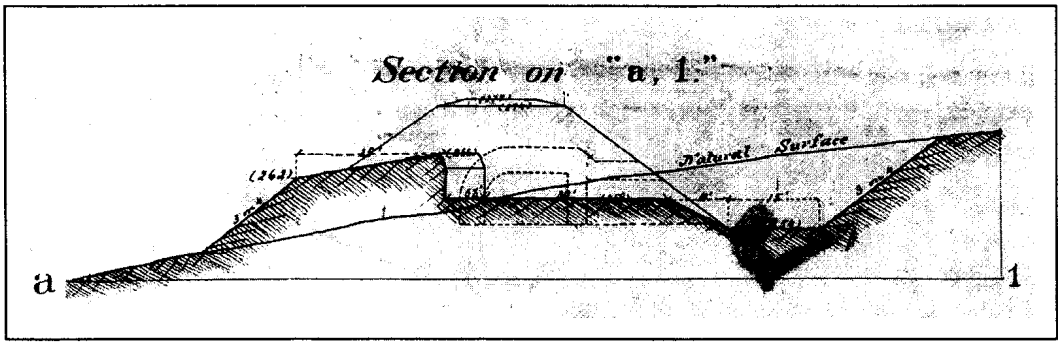

Figure 30. *Section "a, 1" through Rodman positions #59 and #60, showing deep road cut (now filled) behind emplacement. (NARA RG77, Drawer 94, Sheet 102)*

When Battery Godfrey was constructed beginning in 1891, gun positions #51 through #58 were demolished along with traverses #24 through #26. Traverse #27 was incorporated into the left flank of Godfrey. Gun positions #59-#60 were buried at this time and the road cut behind the emplacement filled by a high bank of earth. This bank, measuring approx. 8 feet high, formed a parados at the south end of the battery that prevented enfilade fire from ships entering the Golden Gate. This embankment was converted into a service road leading to a dump constructed on the forward slope of Battery Godfrey sometime around 1940.

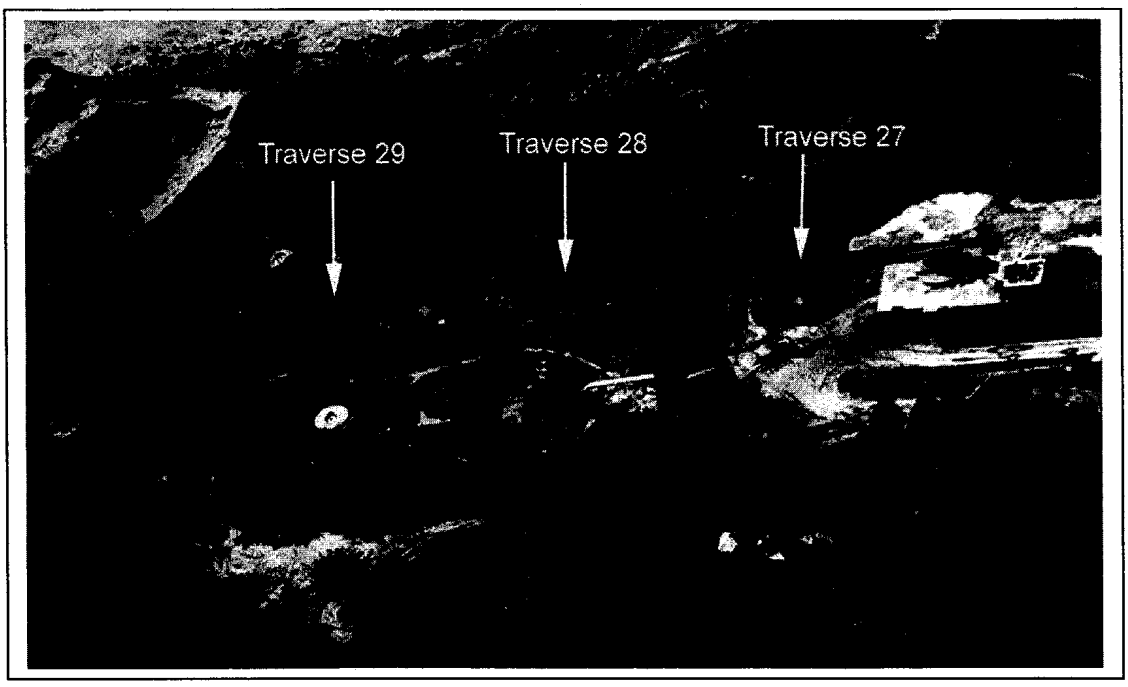

Figure 31. *The three 1870s traverses on the left flank of Battery Godfrey are visible in this February 1942 view. The curved landform between #27 and #28 is a parados constructed to protect the left flank of Godfrey. Tire tracks probably indicate dump activities on the forward slope. Remedial site BBDA 2A. (PARC, GOGA, Cooper Coll.)*

A detailed survey of the topography of the dump area was prepared by the 663rd Engineer Topographic Company in July 1954. It showed the general area of the dump, access roads, and proposed locations for new salvage shop and reclamation bins. It also showed that the reference elevation for the dump access road across the former Rodman positions was 262 feet, and the elevation of the surviving historic road behind the traverses was 255 feet – a difference of only one foot from the 1870 road elevation.[46]

This filling episode also explains why the entrance door to Traverse #27 is located so far below current grade; the magazines lintel is at the historic road level while the adjacent service roads leading to Battery Godfrey and the 1940s dump are built atop seven to eight feet of fill that formed the 1890s parados.

Today this road over the Rodman positions serves as the unpaved access road to the Fort Scott Overlook, and is designated remedial site BBDA 2A.

C. Alterations to Superior Slopes

As part of the construction of the Endicott batteries, the area immediately in front of each gun emplacement (the *superior slope*) was cleared and graded to give the weapon a clear field of fire towards the Golden Gate. Each slope had a downward angle of this slope based on the lowest declination the gun barrel could be depressed below horizontal. In a major-caliber battery, the portions of the superior slope closest to the gun were constructed of concrete. At a distance from the muzzle, however, the material changed to graded and sodded earth. In order to prevent the weapon's powerful muzzle blast from tearing up the earthen slope, a thin concrete extension called a "blast apron" was frequently to the concrete superior slope – usually based on experience with the gun's particular firing characteristics.

The following illustration of Battery Marcus Miller shows both the masonry and earthen superior slopes that were incorporated into its design. (See Figure 32.)

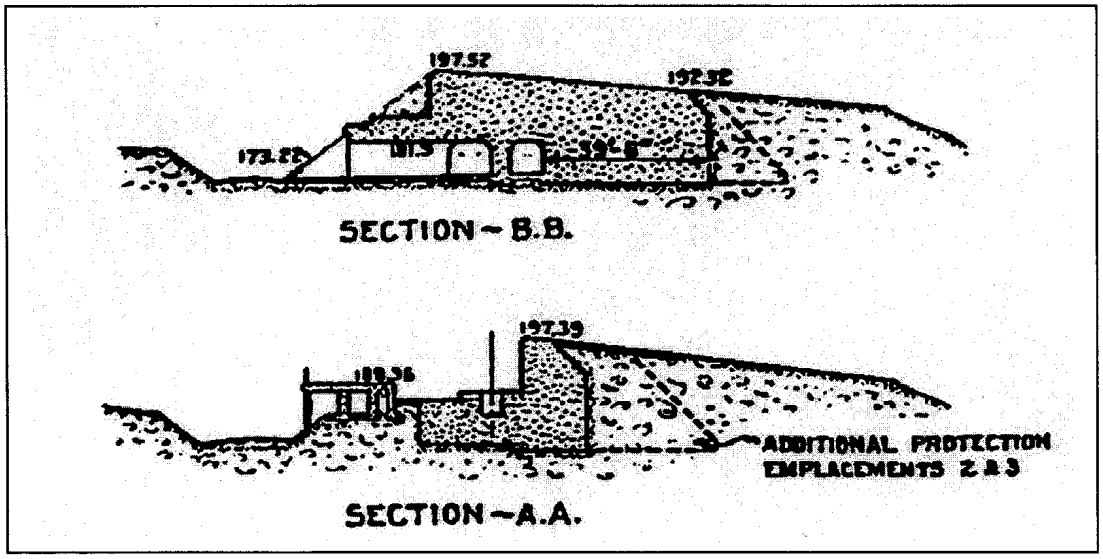

Figure 32. *Sections through two portions of Battery Marcus Miller. Note the impressive thickness of the concrete in front of the magazines (upper). (Report of Completed Works, Form 7, Marcus Miller)*

Due to the increasing elevations of the batteries south of Fort Point, each emplacement's superior slope ended up at a slightly different elevation from the adjacent battery. These differing slope heights created a visibly terraced, or "stair stepped," landscape when viewed from the ocean. (See Figure 33.)

When the batteries were active defensive installations, these superior slopes were kept totally free of trees and any large vegetation that might obscure the field of fire. As time progressed and the guns became obsolete, though, the army ignored the superior slopes and their once-clean grades and profiles were eventually softened by vegetation spread and erosion. Portions of the graded slopes and terraces are still known to exist beneath the brush and tree cover that grows in the area today, and are periodically exposed to view when the park carries out vegetation removal clearing projects.[47]

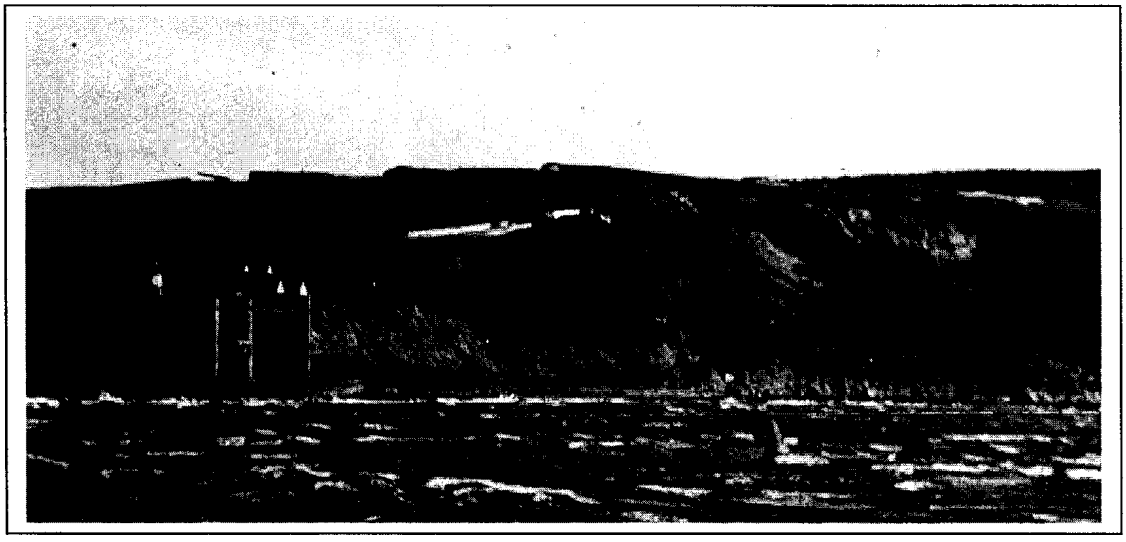

Figure 33. *The terraced superior slopes of Endicott era batteries are visible above Fort Point in this view taken c1900. A 12-inch disappearing rifle at Battery Lancaster appears at left. (California Historical Society)*

D. Filling Activities Adjacent to Batteries.

The access road paralleling the line of Fort Scott batteries has its origins in the original service road constructed in the early 1870s to serve the gun emplacements at West Battery. Over the years, this road has frequently been referred to as a "covered way", based on the assumption that the road was constructed with high sides to protect it from enemy fire.

Actually, the road was not originally constructed as a feature sunken below ground level. When first constructed the road's level was roughly at the same elevation as the surrounding landscape. This landscape, however, has been raised over the decades as a result of grading activities associated with the Endicott fortifications and other construction events.

The earliest map of the West Battery road indicates that the height of the outboard shoulder (i.e., the side away from the gun positions) varied from exactly ground level to a height of 19 feet above the road's surface. The lowest areas were behind the Rodmans on the site of today's Batteries Cranston and Marcus Miller, where the shoulder was at grade, while the highest slope was behind the Rodmans on the site of present day Battery Godfrey. For most of its length, the outboard shoulder was usually only one or two feet in height.[48]

These elevations would start to change when work began on constructing the Endicott batteries that replaced West Battery, and land that had previously been at grade was suddenly raised by several feet. The theory is that the vast quantities of earth and sand removed to make way for the new batteries were spread atop the natural terrain behind the batteries, resulting in a significant increase to the area's elevation.

For comparison purposes, I chose an arbitrary spot 50 feet east of Battery Marcus Miller gun #3, and tracked its elevation changes over the last 160 years. (Except for the last entry, all elevations are based on US Army Engineer surveys.)

Year	*Surveyed elevation*[49]
1847	Approx. 190 feet
1870	190 feet
1871	189 feet
1891	198 feet
1914	198 feet
1945	195-198 feet
2000	205 feet

The park's GIS expert has compared the relative accuracies of these historic surveys, and believes that they are correct to within .75 foot.[50] Given this variance, it is believed the terrain behind Battery Marcus Miller has been raised somewhere in the vicinity of 12 to 15 feet since 1847.

These filling activities appear to have occurred in two significant episodes: 1871-1891, and 1945-2005. The first episode, which resulted in an 8 foot elevation change, is probably associated with the construction of the Endicott batteries. Work began in 1891 on excavations for Batteries Marcus Miller and Godfrey, which coincides with this first increase.

These excavations were immense, and must have resulted in vast quantities of spoil. For example, the area occupied by Battery Marcus Miller measures 560 feet in length x 65 feet deep x 120 feet wide. An excavation this size would conservatively result in 161,177 cubic yards of spoil. It is theorized that this removed material was spread atop the natural hillside behind the batteries – the nearest flat dumping area adjacent to the battery site.

There is also the possibility that additional filling took place behind the batteries during construction of the Golden Gate Bridge toll plaza in 1936-1937. Photographs document that during this period, much of East Battery on the other size of the plaza was

extensively filled. This activity resulted in the creation of today's Battery East Parking Lot adjacent to Lincoln Blvd.[51] However; any filling on the south side of the bridge approach likely took place close to the toll plaza and outside the current project areas.

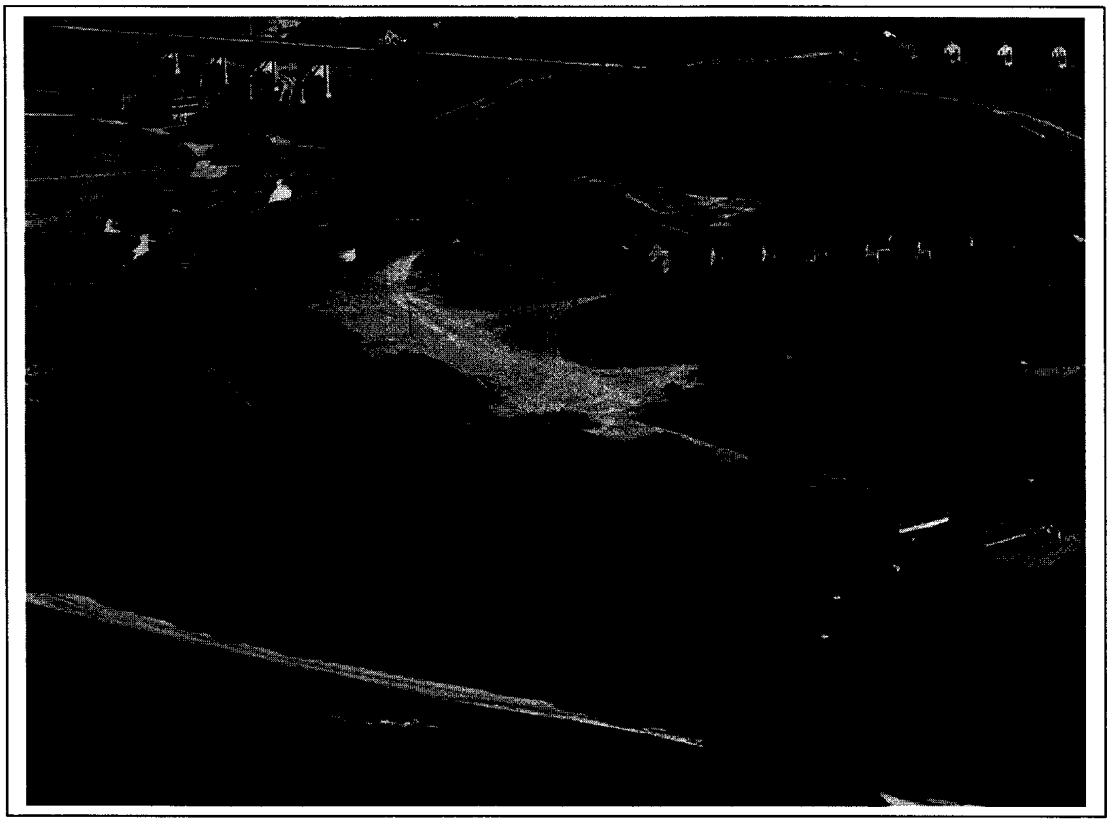

Figure 34. *East Battery partly filled in, October 1937. Compare to 1934 conditions in Figure 13. (Courtesy GG Bridge, Hwy & Trans. Dist.)*

The source of the second episode behind Marcus Miller (an increase of 7 feet) is harder to pin down but probably occurred during the 1960s. The previously cited 1967 aerial photograph in the Golden Gate Bridge collection shows extensive filling operations occurring on the sites of both the Fort Scott dump and also behind Batteries Marcus Miller and Cranston. In this photo, the area between the batteries and Merchant Road is covered with freshly-dumped piles of light-colored fill, each pile corresponding to about the capacity of a dump truck. Tire tracks can be seen among the piles, indicating dumping is still taking place.

The source of the fill is unknown, but could have been come from excavations for the 'new' Letterman General Hospital on the Presidio, where construction was just getting started about this time. The area being filled is bounded roughly by the batteries on the west, Merchant Road on the south, and the Golden Gate Bridge employee parking lot. Today, this area is covered by extensive growths of non-native vegetation and trees; additional (but informal) parking areas, many of them abandoned; and temporary modular office buildings associated with the Golden Gate Bridge's administration.

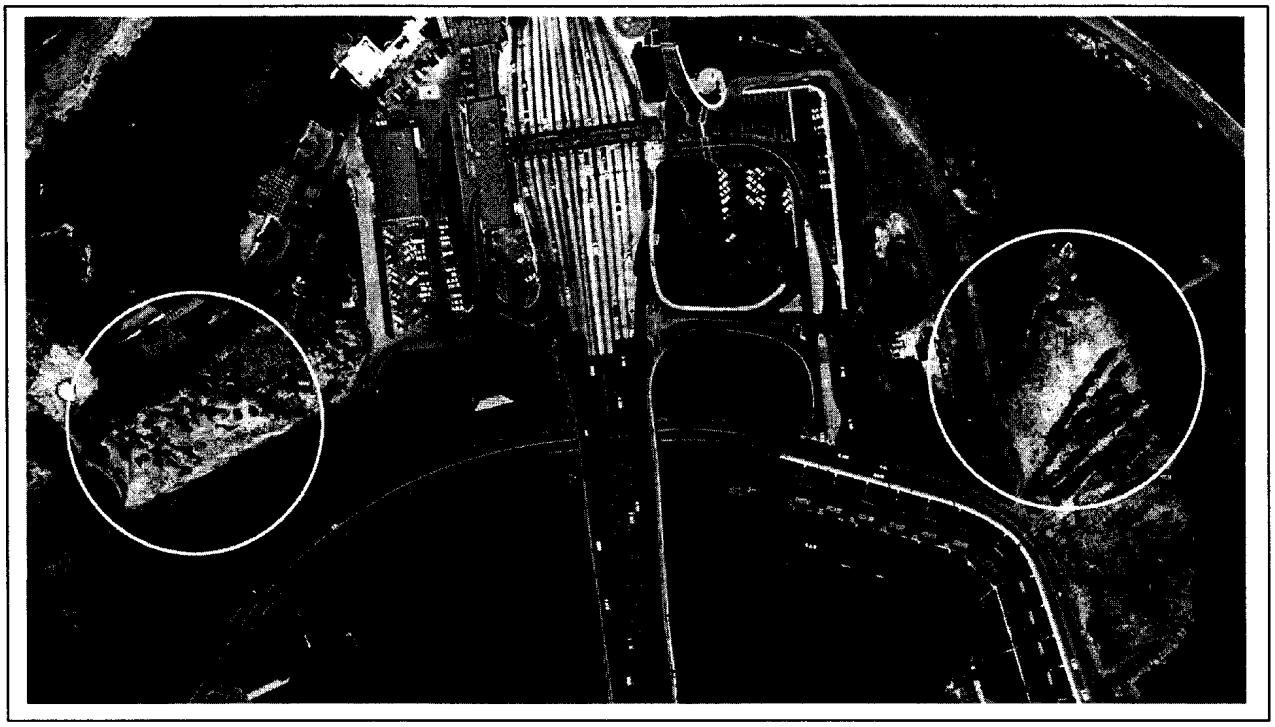

Figure 35. *Dumping activities occurring near Golden Gate Bridge toll plaza in May 1967. Battery Marcus Miller area at left, East Battery area at right. (Courtesy GG Bridge, Hwy & Trans. Dist.)*

In short, today's deeply sunken "covered way" behind Battery Marcus Miller is not a vestige of the Plan of 1870s earthworks but rather the result of Endicott-era and later filling activities. The historic grade in this area should be considered the elevations that existed following completion of the Endicott works.

[47] The author of this report directed once such project in the late 1980s at Battery Marcus Miller. The clearing work was carried out by members of the San Francisco Conservation Crew, and extensive areas of earthen slopes and berms became discernible after clearing dense brush from the superior slopes. These outlines disappeared within a year, though, to returning vegetation.

Abbreviations Key:

HSA - Hollow Stem Auger	c - Cohesion	CU - Consolidated Undrained
MC - Modified California Sampler	DD - Dry Density	KJm - Melange
SPT - Standard Penetration Test Sampler	TD - Total or Wet Density	sp - Serpentinite
N-60 - Hammer energy and sample type corrected blow count	LL - Liquid Limit	Qls - Landslide Deposits
Phi Meyerhof - Internal friction angle (Phi) based on Meherhof table in EPRI, August 1990	PL - Plastic Limit	afo - Other fill
Su - Undrained shear strength	PI - Plasticity Index	Qcol - Colma Fm/Native Soils
Su = N/8 - Shear strength relationship based on N_60, EPRI, August 1990	tsf - tons (2000 pounds) per square feet	afh - Battery West Historic Fill; most recent construction and still in place.
Eff_Stress - Effective overburden stress	ksf - kips (l000 pounds) per square feet	afh1 - Battery West Historic Fill; disturbed on bluff top.
C_N - Overburden correction factor	psf - pounds per square feet	afh2 - Battery West Historic Fill; disturbed downslope.
N1,60 - N60 value corrected for overburden	pcf - pounds per cubic foot	afw - Waste Fill
ft - Feet	y - Sieve analyses was done on sample	
PLLW - Presidio Low Level Water	c_DS - Consolidated Drained Direct Shear	
bgs - Below ground surface	DS - Direct Shear	
UU - Unconsolidated Undrained	UC - Unconfined Compression	
Su_UU - Unconsolidated Undrained Shear Strength	NP - Not Plastic

Table C2-3. Definition of Qualifiers
Field Investigation Report
Baker Beach Disturbed Areas 1, 1A, 2, and 2A
Presidio of San Francisco, California

Summary of Analyte Qualifiers Used in this Report

Type	Qualifier	Qualifier Description — Qualifiers are listed as validation qualifier / lab qualifier where applicable (e.g. J/J+)
Inorganic/ Organic	J	Data are qualified as estimated. It is not possible to assess the direction of the potential bias. False positives or false negatives are unlikely to have been reported.
Inorganic/ Organic	J-	Data are qualified as estimated, with a low bias likely to occur. False positives or false negatives are unlikely to have been reported.
Inorganic/ Organic	J+	Data are qualified as estimated, with a high bias likely to occur. False positives or false negatives are unlikely to have been reported.
Inorganic/ Organic	U	Data are qualified as nondetected, because the analyte was observed in an associated laboratory or field blank.
Inorganic/ Organic	A	Data has been validated and no qualifiers were applied.
Inorganic/ Organic	UJ	The analyte was not detected above the reported sample quantization limit. However, the reported quantization limit is approximate and may or may not represent the actual limit of quantization necessary to accurately and precisely measure the analyte in the sample.
Inorganic/ Organic	C	Presence confirmed, but RPD between columns exceeds 40%.
Inorganic/ Organic	b	Analytical problems were encountered. See the associated case narrative in data package from lab.
Inorganic/ Organic	H	Heavier hydrocarbons contributed to the quantification.
Inorganic/ Organic	L	Lighter hydrocarbons contributed to the quantification.
Inorganic/ Organic	Y	Sample exhibits chromatographic pattern that does not resemble standard.
Inorganic/ Organic	YZ	Indicates that quantization is based only on a single peak or peaks and that the chromatogram does not resemble a fuel pattern.
Inorganic/ Organic	Z	Indicates that the chromatogram resembles the requested standard, but includes a single peak that significantly biases the quantization.

Footnotes:

Results exceeding cleanup levels are outlined with a box.

Sample data is provided on a dry weight basis.

ND = Not Detected at the specific reporting level in parentheses.

NT = Not Tested

Analytical tables present results for compounds that were detected in any of the samples collected from the site.

Results for non-detect compounds are listed on tables in Appendix C2.

Notes: Where validation qualifiers are absent, data was used for screening purposes.

APPENDIX C3

DATA VALIDATION

TO: Gary Lieberman, Mactec E & C, Inc. March 15, 2006

FROM: Donna Breaux, DataVal, Inc.

DATA VALIDATION SUMMARY REPORT FOR THE BAKER BEACH SITE, THE PRESIDIO OF SAN FRANCISCO, CA

LABORATORY: Curtis & Tompkins Laboratories, Berkeley, CA

SAMPLING DATES: April 7 - 28, May 4 - 27, August 1 and October 3 thru 10, 2005

Data validation of Level III and Level IV laboratory data packages was performed according to the project-specific guidelines. These guidelines were outlined in the Presidio-wide Quality Assurance Project Plan, Sampling and Analysis Plan, April, 2001; the U. S. Environmental Protection Agency Contract Laboratory Program National Functional Guidelines for Chlorinated Dioxin/Furan Data Review, August, 2002; the U. S. Environmental Protection Agency Contract Laboratory Program National Functional Guidelines for Organic Data Review, October, 1999; and the U. S. Environmental Protection Agency Contract Laboratory Program National Functional Guidelines for Inorganic Data Review, October, 2004.

The data were reviewed for holding times, blanks, GC/MS tunes, initial calibrations, continuing calibration verification (CCV) standards, performance evaluation mix (PEM) standards, surrogate recoveries, internal standards, laboratory control samples (LCS), laboratory duplicate samples, matrix spikes (MS), matrix spike duplicates (MSD), ICP interference check standards, ICP serial dilutions, field QC blanks, field duplicate samples and compound identification and quantitation.

The following paragraphs highlight the essential findings of the data validation effort:

I. **Volatile Organic Compounds by GC/MS (8260B)**

Overall, the data are usable as reported with any added qualifiers. Qualifications were required for the reasons noted in Sections C, F, H and J.

A. Reporting Limits

The laboratory reporting limits for VOCs in water and soil matrix samples met the project required reporting limits, with the following exceptions:

1. It should be noted that the reporting limits for all soils were raised due to dry weight correction.
2. The following table lists the compounds which the laboratory reporting limits did not meet the project required reporting limits listed in Table 2-6.8-1 of the QAPP.

Reviewed: MJH

Compound	Matrix	Laboratory Reporting Limit	Project Required Reporting Limit
Acetone	Soil	20 ug/kg	10 ug/kg
Methylene chloride	Soil	20 ug/kg	5 ug/kg
Vinyl acetate	Soil	50 ug/kg	10 ug/kg
Bromoform	Water	1.0 ug/L	0.5 ug/L
Bromomethane	Water	1.0 ug/L	0.5 ug/L
Chloroethane	Water	1.0 ug/L	0.5 ug/L
Chloromethane	Water	1.0 ug/L	0.5 ug/L
Methylene chloride	Water	10 ug/L	4.5 ug/L

B. Holding Times

Technical holding time criteria specified in the analysis method were met for all project samples. Soil samples BBSB108(0.0), BBSB108(2.0), BBSB109(0.0), DUP(050512), BBSB109(2.0), BB2ASB112(0.5), BB1SB113(0.5), BB1SB114(0.5) and BBITP113(5.5) were collected in Encore samplers. The samples listed above were analyzed by the laboratory past the recommended 48-hour holding time. Since the samples were kept under refrigeration at the specified temperature ($2^{o}C$ to $6^{o}C$) until analysis, the results were accepted without qualification. In the professional judgment of the reviewer, the data were acceptable as reported.

C. Blanks

Target analytes were not observed in the trip blank associated with the project samples. Target analytes were not observed in any laboratory method blanks associated with the project samples, with the following exceptions:

1. Laboratory method blank QC295690 had a detected level of naphthalene at 2.1 ug/L. The associated samples were non-detect for naphthalene, and qualification was not required.
2. Laboratory method blank QC292135 had a detected level of methylene chloride at 4.0 ug/kg. The associated samples were either non-detect for methylene chloride, or had values for methylene chloride greater than ten times the blank amount, and qualification was not required.
3. Laboratory method blank QC292755 had a detected level of methylene chloride at 1.9 ug/kg. All results less than 10 times the blank amount were affected by this contamination. The detected results for methylene chloride in the associated project samples were changed to non-detect (U) if those values were less than ten times the blank amount.

See Table 2 of this report for a summary of qualifications due to blank contamination.

D. GC/MS Tunes

All QC criteria were met for the GC/MS tunes associated with the project samples.

E. Initial Calibration

Initial calibration criteria were met for all initial calibration standards associated with the project samples.

F. Continuing Calibration

Continuing calibration criteria were met for all continuing calibration verification (CCV) standards associated with the project samples, with the following exceptions:

1. Qualification was not required for samples with non-detect results associated with high-failing continuing calibration standards (%D > +25%). Those failures were not noted in this report.
2. The 6/1/05 at 09:42 water matrix CCV analyzed on instrument MSVOA04 had one compound with a percent difference less than -25%, 2,2-dichloropropane (-44%). The associated samples were non-detect for this compound and qualified as estimated (UJ).
3. The 10/6/05 at 09:26 soil matrix CCV analyzed on instrument MSVOA06 had one compound with a percent difference less than -25%, carbon disulfide (-27%). The associated samples were non-detect for this compound and qualified as estimated (UJ).

See Table 2 of this report for a summary of qualifications due to continuing calibration percent difference failure.

G. Internal Standards

Internal standard QC acceptance criteria were met for all project samples.

H. Surrogate Recoveries

Surrogate spike recoveries met QC acceptance criteria for all project samples, with the following exceptions:

1. Five project soil samples had high-failing percent recoveries outside the 59%-113% project acceptance criteria for surrogate 4-bromofluorobenzene. The detected results in samples BB2ATP104(8.0), BB2ATP100(1.0), BB2ATP101(14.0), BB1TP102(4.0) and BB1TP108(5.0), were qualified as estimated with a high bias (J+). It should be noted that the detected result for methylene chloride in sample BB1TP108(5.0) was changed to non-detect due to method blank contamination, and qualification for surrogate recovery failure was not required. Qualification was not required for non-detected results.

See Table 2 of this report for a summary of qualifications due to surrogate percent recovery failure.

I. Laboratory Control Samples

All QC criteria were met for the laboratory control samples associated with the project samples.

J. Matrix Spike/Matrix Spike Duplicate

All QC criteria were met for the matrix spikes and matrix spike duplicates associated with the project samples, with the following exceptions:

1. The percent recoveries for trichloroethene were outside the 65%-135% project acceptance criteria in QC samples 178983-001 MS/MSD at 162% and 163%, respectively. The parent sample was associated with a site unrelated to the project site and qualification was not required. QC Batch 101317
2. The percent recovery for 1,1-dichloroethene was outside the 65%-135% project acceptance criteria in QC sample in BB1TP108(5.0) MS at 136%. The parent sample was non-detect for 1,1-dichloroethene, and qualification was not required. QC Batch 101759
3. The percent recoveries were outside the 65%-135% project acceptance criteria in QC samples BBSB108(0.0) MS/MSD for benzene (64%/52%), toluene (57%/44%), chlorobenzene (47%/34%) and trichloroethene (okay/50%). The parent sample was non-detect for these compounds and qualified as estimated (UJ). QC Batch 102044

See Table 2 of this report for a summary of qualifications due to matrix spike percent recovery failure.

K. Compound Identification and Quantitation

Samples BBD2TP105(11.5) (179182-001), BBD2TP105(15.0) (179182-002), BBD2TP106(2.0) (179182-003), BBSB119(2.5) (182357-001) and BBSB119(4.5) (182357-002) received full (Level IV) data validation. This included re-calculation of GC/MS tunes, initial and continuing calibrations, surrogate values, and internal standard areas; in addition to re-calculation of all reported results for VOCs in these samples. The results for VOCs were verified as correctly reported by the laboratory.

II. Polynuclear Aromatic Hydrocarbons (PAHs) by GC/MS (8270C-SIM)

Overall, the data are usable as reported with any added qualifiers. Qualifications were required for the reasons noted in Sections C, F, G, H and I.

A. Reporting Limits

The laboratory reporting limits for PAHs in soil and water matrix samples met the project required reporting limits. It should be noted that the reporting limits for all soils were raised due to dry weight correction.

B. Holding Times

Technical holding time criteria were met for all project samples.

C. Blanks

Target analytes were not observed in any laboratory method blanks associated with the project samples, with the following exceptions:

1. Laboratory method blank QC296175 had detected levels of phenanthrene at 0.03 ug/L, fluoranthene at 0.03 ug/L, chrysene at 0.02 ug/L, and benzo(a)anthracene at 0.02 ug/L. The associated sample was non-detect for benzo(a)anthracene, and qualification was not required. The detected results for phenanthrene, fluoranthene and chrysene in the associated sample were changed to non-detect (U).
2. Laboratory method blank QC313307 had detected levels of phenanthrene at 0.99 ug/kg, fluoranthene at 2.1 ug/kg, pyrene at 2.9 ug/kg, benzo(a)anthracene at 2.7 ug/kg, chrysene at 2.2 ug/kg, benzo(b)fluoranthene at 3.3 ug/kg, benzo(k)fluoranthene at 3.7 ug/kg, benzo(a)pyrene at 3.0 ug/kg, indeno(1,2,3-cd)pyrene at 3.8 ug/kg, dibenz(a,h)anthracene at 3.2 ug/kg and benzo(g,h,i)perylene at 4.0 ug/kg. The detected results for these compounds in the associated samples were changed to non-detect (U) if those values were less than five times the blank amounts.

See Table 2 of this report for a summary of qualifications due to blank contamination.

D. GC/MS Tunes

All QC criteria were met for the GC/MS tunes associated with the project samples.

E. Initial Calibration

Initial calibration criteria were met for all calibration standards associated with the project samples.

F. Continuing Calibration

Continuing calibration criteria were met for all continuing calibration verification standards associated with the project samples with the following exceptions:

1. The 5/17/05 at 20:04 soil matrix CCV analyzed on instrument MSBNA03 had three compounds with percent differences greater than +25%: indeno(1,2,3-cd)pyrene (+36%), dibenz(a,h)anthracene (+39%) and benzo(g,h,i)perylene (+28%). The associated samples were non-detect for indeno(1,2,3-cd)pyrene and dibenz(a,h)anthracene, and qualification was not required. The detected results for benzo(g,h,i)perylene in the associated samples were qualified as estimated with a high bias (J+).
2. The 10/19/05 at 08:44 soil matrix CCV analyzed on instrument MSBNA03 had one compound with a percent difference greater than +25%: naphthalene (+28%). The detected results for naphthalene in the associated samples were qualified as estimated with a high bias (J+).

3. The 10/27/05 at 10:19 soil matrix CCV analyzed on instrument MSBNA04 had one compound with a percent difference greater than +25%: indeno(1,2,3-cd)pyrene (+41%). The detected results for indeno(1,2,3-cd)pyrene in the associated samples were qualified as estimated with a high bias (J+).
4. Qualification was not required for samples with non-detect results associated with high-failing continuing calibration standards. Those failures were not noted in this report.

See Table 2 of this report for a summary of qualifications due to continuing calibration percent difference failure.

G. Internal Standards

Internal standard QC acceptance criteria were met for all project samples with the following exceptions:

1. The area counts for internal standard perylene-d12 were outside the -50% acceptance criteria in project samples BBD2TP106(2.0) (179182-003), DUP(050405) (179266-004), BB1TP108(5.0) (179266-007), BB29B102(2.0) (179445-003), BBSB108(0.0) (179445-004), BBSB109(0.0) (179445-006) and DUP(050512) (179445-007). The compounds associated with this internal standard were qualified as estimated with a low bias (J-/UJ).
2. The area counts for internal standards chrysene-d12 and perylene-d12 were outside the -50% acceptance criteria in project sample BBITP113(3.0) (182254-003). The compounds associated with this internal standard were qualified as estimated with a low bias (J-/UJ).

See Table 2 of this report for a summary of qualifications due to internal standard area count failure.

H. Surrogate Recoveries

Surrogate spike recoveries met QC acceptance criteria for all project samples, with the following exceptions:

1. The percent recoveries for surrogates nitrobenzene-d5 and terphenyl-d14 were outside of the project acceptance limits in sample BB1TP106(6.0) (179266-001) at 123% and 142%, respectively; and sample DUP(050405) (179266-004) at 133% and 140%, respectively. The detected results in these samples were qualified as estimated with a high bias (J+). Qualification was not required for non-detected results.

See Table 2 of this report for a summary of qualifications due to surrogate percent recovery failure.

I. Laboratory Control Samples

All QC criteria were met for the laboratory control samples associated with the project samples, with the following exception:

1. The percent recovery for acenaphthene was outside the 36% - 111% project acceptance criteria in laboratory control sample QC294077 at 117%. The detected results for acenaphthene in the associated samples were qualified as estimated with a high bias (J+). Qualification was not required for non-detected results. QC Batch 102111

J. Matrix Spike/Matrix Spike Duplicate

All QC criteria were met for the matrix spikes and matrix spike duplicates associated with the project samples, with the following exception:

1. The percent recovery for pyrene was outside the 35% - 142% project acceptance criteria in QC sample 179646-029 MSD at 183%. The parent sample was associated with a site unrelated to the project site, and qualification was not required. QC Batch 102619

K. Compound Identification and Quantitation

Samples BBD2TP105(11.5) (179182-001), BBD2TP105(15.0) (179182-002), BBD2TP106(2.0) (179182-003), BBSB119(2.5) (182357-001) and BBSB119(4.5) (182357-002) received full (Level IV) data validation. This included re-calculation of GC/MS tunes, initial and continuing calibrations, surrogate values, and internal standard areas; in addition to re-calculation of all reported results for PAHs in these samples. The results for PAHs were verified as correctly reported by the laboratory.

III. Dioxins and Furans by High Resolution GC/MS (8290)

Overall, the data are usable as reported. Qualification was not required.

A. Reporting Limits

The laboratory reporting limits for dioxins and furans in soil and water matrix samples met the project required reporting limits. It should be noted that the reporting limits for all soils were raised due to dry weight correction.

B. Holding Times

Technical holding time criteria were met for all project samples.

C. Blanks

Target analytes were not observed in any laboratory method blanks associated with the project samples, with the following exception:

1. Laboratory method blanks 64980, 65028 , 65087 and 65208 had detected levels of various target analytes. The associated samples were either non-detect for those analytes, or the levels in the samples were greater than five times the blank amounts, and qualification was not required.

D. GC/MS System Performance Check
All QC criteria were met for the GC/MS mass calibration and column performance check standards associated with the project samples.

E. Initial Calibration
Initial calibration criteria were met for all calibration standards associated with the project samples.

F. Continuing Calibration
Continuing calibration criteria were met for all continuing calibration verification standards associated with the project samples.

G. Internal Standards
Internal standard recoveries met QC acceptance criteria for all project samples.

H. Laboratory Control Samples
All QC criteria were met for the laboratory control samples associated with the project samples.

I. Matrix Spike/Matrix Spike Duplicate
All QC criteria were met for the matrix spike and matrix spike duplicates associated with the project samples with the following exceptions:

1. The percent recoveries for three target compounds failed the 50% - 150% project acceptance criteria in QC sample 402-11-3 MSD. The parent sample was associated with a site unrelated to the project site, and qualification was not required.
2. The percent recoveries for three target compounds failed the 50% - 150% project acceptance criteria in QC samples 402-96-6 MS and/or MSD. The parent sample was associated with a site unrelated to the project site, and qualification was not required.

J. Compound Identification and Quantitation
Samples analyzed for dioxins and furans did not receive full (Level IV) data validation.

IV. Total Petroleum Hydrocarbons - Gasoline Range (8015B)

Overall, the data are usable as reported with any added qualifiers. Qualifications were required for the reasons noted in Sections C, F and H.

A. Reporting Limits
The laboratory reporting limits for TPH – gasoline in water and soil matrix samples met the project required reporting limits. It should be noted that the reporting limits for all soils were raised due to dry weight correction.

B. Holding Times
Technical holding time criteria were met for all project samples.

C. Blanks

Target analytes were not observed in any laboratory method blanks or trip blanks associated with the project samples, with the following exceptions:

1. Trip blank TB-1 (179714-002) had a detected level of TPH-gasoline at 11 ug/L. All results less than 5 times the blank amount were affected by this contamination. The detected result for TPH-gasoline in project sample BB1PZ101 (179714-001) was changed to non-detect (U).
2. Laboratory method blank QC295383 had a detected level of TPH-gasoline at 11 ug/L. Values for TPH-gasoline less than five times the blank amount were affected by this contamination. The results for TPH-gasoline in project samples BB1PZ101 and TB-1 were changed to non-detect (U).
3. Laboratory method blank QC291612 had a detected level of TPH-gasoline at 20 ug/kg. The associated samples were non-detect for TPH-gasoline, and qualification was not required.
4. Laboratory method blank QC291334 had a detected level of TPH-gasoline at 19 ug/kg. The associated samples were non-detect for TPH-gasoline, and qualification was not required.
5. Laboratory method blank QC311317 had a detected level of TPH-gasoline at 0.021 mg/kg. Values for TPH-gasoline less than five times the blank amount were affected by this contamination. The results for TPH-gasoline in project samples BBITP110(8.0), BBITP110(12.0), BBITP113(3.0), BBITP113(5.5), BBITP111(1.5), BBITP111(6.0), BBITP111(3.0) and BBITP110(1.5) were changed to non-detect (U) since the sample values were less than five times the blank amount.
6. Laboratory method blank QC312369 had a detected level of TPH-gasoline at 0.018 mg/kg. Values for TPH-gasoline less than five times the blank amount were affected by this contamination. The results for TPH-gasoline in project samples BBSB119(2.5) and BBSB119(4.5) were changed to non-detect (U) since the sample values were less than five times the blank amount.

See Table 2 of this report for a summary of qualifications due to blank contamination.

D. Initial Calibration

Initial calibration criteria were met for all calibration standards associated with the project samples.

E. Continuing Calibration

Continuing calibration criteria were met for all continuing calibration verification standards associated with the project samples.

F. Surrogate Recoveries

Surrogate spike recoveries met QC acceptance criteria for all project samples, with the following exception:

1. The percent recoveries for surrogate 4-bromofluorobenzene were outside the 65%-135% project acceptance criteria in samples BBSB109(0.0) at 56% and DUP(050512) at 60%. The non-detected result for TPH-gasoline in sample BBSB109(0.0) were qualified as estimated (UJ). The detected result for TPH-gasoline in sample DUP(050512) was qualified as estimated with a low bias (J-).

See Table 2 of this report for a summary of qualifications due to surrogate percent recovery failure.

G. Laboratory Control Samples

All QC criteria were met for the laboratory control samples associated with the project samples.

H. Matrix Spike/Matrix Spike Duplicate

All QC criteria were met for the matrix spikes and matrix spike duplicates associated with the project samples, with the following exceptions:

1. The percent recovery for TPH-gasoline was outside the 65%-135% project acceptance criteria in QC sample 179425-001 MS at 58%. The parent sample was associated with an unrelated site, and qualification was not required. QC Batch 101984
2. The percent recoveries for TPH-gasoline were outside the 65%-135% project acceptance criteria in QC samples BBSB108(0.0) MS/MSD at 45% and 45%, respectively. The parent sample was non-detect for TPH-gasoline and qualified as estimated (UJ). QC Batch 101984
3. The percent recovery for TPH-gasoline was outside the 65%-135% project acceptance criteria in QC sample 179425-004 MS at 58%. The parent sample was associated with a site unrelated to the project site, and qualification was not required. QC Batch 101984

See Table 2 of this report for a summary of qualifications due to matrix spike percent recovery failure.

I. Compound Identification and Quantitation

Samples BBD2TP105(11.5) (179182-001), BBD2TP105(15.0) (179182-002), BBD2TP106(2.0) (179182-003), BBSB119(2.5) (182357-001) and BBSB119(4.5) (182357-002) received full (Level IV) data validation. This included re-calculation of initial and continuing calibrations, and surrogate values; in addition to re-calculation of the reported results for TPH-gasoline in these samples. The results for TPH - gasoline were verified as correctly reported by the laboratory.

V. Total Petroleum Hydrocarbons – Diesel/Fuel Oil (8015B)

Overall, the data are usable as reported with any added qualifiers. Qualifications were required for the reasons noted in Sections C, F and H.

A. Reporting Limits

The laboratory reporting limits for TPH–diesel and fuel oil in water and soil matrix samples met the project required reporting limits. It should be noted that the reporting limits for all soils were raised due to dry weight correction.

B. Holding Times

Technical holding time criteria were met for all project samples.

C. Blanks

Target analytes were not observed in any laboratory method blanks associated with the project samples, with the following exceptions:

1. Laboratory method blank QC292456 had a detected level of TPH-fuel oil at 0.37 mg/kg. Values for TPH-fuel oil less than five times the blank amount were affected by this contamination. The result for TPH-fuel oil in project sample BBD2TP105(15.0) was changed to non-detect (U).
2. Laboratory method blank QC292868 had a detected level of TPH-diesel 0.48 mg/kg. Values for TPH-diesel less than five times the blank amount were affected by this contamination. The result for TPH-diesel in project sample BB1TP106(2.5) was changed to non-detect (U).

See Table 2 of this report for a summary of qualifications due to blank contamination.

D. Initial Calibration

Initial calibration criteria were met for all calibration standards associated with the project samples.

E. Continuing Calibration

Continuing calibration criteria were met for all continuing calibration verification standards associated with the project samples.

F. Surrogate Recoveries

Surrogate spike recoveries met QC acceptance criteria for all project samples, with the following exceptions:

1. Samples with failing surrogate recoveries which required dilutions of five-fold or greater did not require qualification and were not included in this report.
2. The percent recovery for surrogate hexacosane was outside the 65%-135% project acceptance criteria in sample DUP(050512) (179445-007) at 140%. The detected results for TPH-diesel and

TPH-fuel oil in this sample were qualified as estimated with a high bias (J+).

3. The percent recovery for surrogate hexacosane was outside the 65%-135% project acceptance criteria in sample BB1TP106(2.5) (179266-003) at 64%. The detected results for TPH-diesel and TPH-fuel oil were qualified as estimated with a low bias (J-).

See Table 2 of this report for a summary of qualifications due to surrogate percent recovery failure.

G. Laboratory Control Samples

All QC criteria were met for the laboratory control samples associated with the project samples.

H. Matrix Spike/Matrix Spike Duplicate

All QC criteria were met for the matrix spikes and matrix spike duplicates associated with the project samples, with the following exceptions:

1. The percent recoveries for TPH-diesel in QC samples 179062-003 MS/MSD were outside the 65%-135% project acceptance criteria at 136% and -220%, respectively. The parent sample was associated with a site unrelated site to the project site and qualification was not required. QC Batch 101505
2. The percent recovery for TPH-diesel in QC sample BB2ATP100(1.0) MSD was outside the 65%-135% project acceptance criteria at 156%. The detected result for TPH-diesel in the parent sample was qualified as estimated with a high bias (J+). QC Batch 101361
3. The percent recoveries for TPH-diesel in QC samples 179446-002 MS/MSD were outside the 65%-135% project acceptance criteria at 6% and 140%, respectively. The parent sample was associated with a site unrelated to the project site and qualification was not required. QC Batch 102056

See Table 2 of this report for a summary of qualifications due to matrix spike percent recovery failure.

I. Compound Identification and Quantitation

Samples BBD2TP105(11.5) (179182-001), BBD2TP105(15.0) (179182-002), BBD2TP106(2.0) (179182-003), BBSB119(2.5) (182357-001) and BBSB119(4.5) (182357-002) received full (Level IV) data validation. This included re-calculation of initial and continuing calibrations, and surrogate values; in addition to re-calculation of the reported results for TPH-diesel and TPH-fuel oil in these samples. The results for TPH-diesel and TPH-fuel oil were verified as correctly reported by the laboratory.

VI. Organochlorine Pesticides (8081A)

Overall, the data are usable as reported with any added qualifiers. Qualifications were required for the reasons noted in Sections D, E, G, H and I.

A. Reporting Limits

The laboratory reporting limits for pesticides in water and soil matrix samples met the project required reporting limits, with the following exceptions:

1. The reporting limits for all soils were raised due to dry weight correction.
2. The laboratory reporting limit did not meet the project required reporting limit listed in Table 2-6.5-1 of the QAPP for toxaphene in soil matrix samples. The laboratory reported 60 ug/kg for this compound. The project required reporting limit was 40 ug/kg.
3. The results for all pesticide compounds in sample BBITP113(3.0) (182254-003) were reported as non-detected at a five-fold dilution due to the nature of the sample matrix. The reporting limits were raised by the dilution factor.
4. The results for all pesticide compounds in sample BBSB119(2.5) (182357-001) were reported as non-detected at a ten-fold dilution due to the nature of the sample matrix. The reporting limits were raised by the dilution factor.

B. Holding Times

Technical holding time criteria were met for all project samples.

C. Blanks

Target analytes were not observed in any laboratory method blanks associated with the project samples, with the following exception:

1. Laboratory method blank QC295453 had a detected level of delta-BHC at 0.005 ug/L. The associated samples were non-detect for delta-BHC, and qualification was not required.
2. Laboratory method blank QC313628 had a detected level of endrin aldehyde at 1.9 ug/kg. The associated samples were non-detect for endrin aldehyde, and qualification was not required.

D. Initial Calibration

Initial calibration criteria were met for all calibration standards associated with the project samples with the following exceptions:

1. The 5/17/05 soil matrix initial calibration analyzed on instrument GC23B had two compounds with percent relative standard deviations (%RSD) greater than the 20% method acceptance criteria: beta-BHC at 28%, and delta-BHC at 24%. The non-detect results for these compounds in the associated samples were qualified as estimated (UJ).
2. The 5/11/05 soil matrix initial calibration analyzed on instrument GC16A had one compound with the %RSD greater than the 20%

method acceptance criteria, 4,4'-DDT at 25%. The result for 4,4'-DDT in the associated sample was qualified as estimated (J).

3. The 9/28/05 soil matrix initial calibration analyzed on instrument GC23A had two compounds with the %RSD greater than the 20% method acceptance criteria, beta-BHC at 27% and delta-BHC at 23%. The non-detect results for these compounds in the associated samples were qualified as estimated (UJ).
4. The 9/28/05 soil matrix initial calibration analyzed on instrument GC23B had one compound with the %RSD greater than the 20% method acceptance criteria, delta-BHC at 21%. The non-detected results for delta-BHC in the associated samples were qualified as estimated (UJ).

See Table 2 of this report for a summary of qualifications due to initial calibration percent RSD failure.

E. Continuing Calibration

Continuing calibration criteria were met for all continuing calibration verification standards associated with the project samples with the following exceptions:

1. Qualification was not required for samples with non-detect results associated with high-failing CCV standards. Those failures were not noted in this report.
2. The 5/3/05 at 23:33 soil matrix CCV analyzed on instrument GC16B had two compounds with percent differences less than -15%, 4,4'-DDT (-35%) and methoxychlor (-26%). The associated samples were non-detect and qualified as estimated (UJ).
3. The 5/18/05 at 16:51 soil matrix CCV analyzed on instrument GC23B had three compounds with percent differences less than -15%, beta-BHC (-21%), delta-BHC (-17%) and endrin aldehyde (-16%). The associated samples were non-detect and qualified as estimated (UJ).
4. The 5/19/05 at 00:06 soil matrix CCV analyzed on instrument GC23B had two compounds with percent differences less than -15%, beta-BHC (-25%) and delta-BHC (-16%). The associated samples were non-detect and qualified as estimated (UJ).
5. The same CCV (5/19/05 at 00:06) had three compounds with percent differences greater than +15%, dieldrin (+18%), 4,4'-DDE (+22%) and 4,4'-DDD (+27%). The associated samples were non-detect for 4,4'-DDE and 4,4'-DDD, and qualification was not required. The detected results for dieldrin in the associated samples were qualified as estimated with a high bias (J+).
6. The 5/13/05 at 00:16 soil matrix CCV analyzed on instrument GC16B had one compound with a percent difference less than -15%, 4,4'-DDT (-16%). The associated samples were non-detect and qualified as estimated (UJ).

7. The 5/4/05 at 04:08 soil matrix CCV analyzed on instrument GC16B had two compounds with percent differences less than -15%, 4,4'-DDT (-21%) and methoxychlor (-20%). The associated samples were non-detect and qualified as estimated (UJ).
8. The 5/3/05 at 23:33 soil matrix CCV analyzed on instrument GC16B had two compounds with percent differences less than -15%, 4,4'-DDT (-35%) and methoxychlor (-26%). The associated samples were non-detect and qualified as estimated (UJ).
9. The 5/13/05 at 12:50 soil matrix CCV analyzed on instrument GC16B had one compound with a percent difference greater than +15%, 4,4'-DDD (+17%). The detected results for 4,4'-DDD in the associated samples were qualified as estimated with a high bias (J+). Qualification was not required for non-detected results.
10. The same CCV (5/13/05 at 12:50) had one compound with a percent difference less than -15%, 4,4'-DDT (-25%). The associated samples were non-detect and qualified as estimated (UJ).
11. The 6/4/05 at 07:53 soil matrix CCV analyzed on instrument GC23B had one compound with a percent difference less than –15%, 4,4'-DDT (-17%). The associated samples were non-detect and qualified as estimated (UJ).
12. The 10/20/05 at 10:18 soil matrix CCV analyzed on instrument GC23A had one compound with a percent difference less than -15%, delta-BHC (-16%). The associated samples were non-detect and qualified as estimated (UJ).
13. The 10/20/05 at 16:44 soil matrix CCV analyzed on instrument GC23A had two compounds with percent differences less than -15%, beta-BHC (-21%) and delta-BHC (-24%). The associated samples were non-detect and qualified as estimated (UJ).

See Table 2 of this report for a summary of qualifications due to continuing calibration percent difference failure.

F. Performance Evaluation Mix (PEM) Check Standards

All PEM check standards met the project degradation criteria of 15% for endrin and 4,4'-DDT.

G. Surrogate Recoveries

Surrogate spike recoveries met QC acceptance criteria for all project samples, with the following exceptions:

1. Samples with failing surrogate recoveries which required dilutions of five-fold or greater did not require qualification and were not included in this report.
2. Samples with non-detect results and high-failing surrogate recoveries did not require qualification, and were not noted in this report.

3. The percent recoveries for surrogate tetrachloro-m-xylene (TCMX) were outside the 65% - 135% project acceptance criteria in samples BB02TP108(7.0) (179089-002) at 62% and BBD2TP105(15.0) (179182-002) at 63%. The compounds associated with this surrogate, alpha-BHC, beta-BHC, delta-BHC, gamma-BHC, aldrin, heptachlor, heptachlor epoxide and endosulfan I, were non-detect and qualified as estimated (UJ).
4. The percent recovery for surrogate decachlorobiphenyl (DCB) was outside the 65%-135% project acceptance criteria in sample BBIPZ101 (179714-001) at 55%. The compounds associated with this surrogate, alpha-chlordane, 4,4'-DDD, 4,4'-DDE, 4,4'-DDT, dieldrin, endosulfan II, endosulfan sulfate, endrin, endrin aldehyde, gamma-chlordane, methoxychlor and toxaphene, were non-detect and qualified as estimated (UJ).
5. The percent recoveries for surrogate TCMX were outside the 65% - 135% project acceptance criteria in samples BBITP110(12.0) (182254-002) at 55%, BBITP110(8.0) (182254-001) at 60%, BBITP111(6.0) (182254-006) at 57% and BBITP113(5.5) (182254-004) at 54%. The compounds associated with this surrogate, alpha-BHC, beta-BHC, delta-BHC, gamma-BHC, aldrin, heptachlor, heptachlor epoxide and endosulfan I, were qualified as estimated with a low bias (J-/UJ).

See Table 2 of this report for a summary of qualifications due to surrogate percent recovery failure.

H. Laboratory Control Samples

All QC criteria were met for the laboratory control samples associated with the project samples with the following exception:

1. The percent recovery for 4,4'-DDT was outside the 65% - 135% project acceptance criteria in laboratory control sample QC292397 at 62%. The non-detected results for 4,4'-DDT in the associated samples were qualified as estimated (UJ). QC Batch 101667

See Table 2 of this report for a summary of qualifications due to laboratory control sample percent recovery failure.

I. Matrix Spike/Matrix Spike Duplicate

All QC criteria were met for the matrix spike and matrix spike duplicates associated with the project samples with the following exceptions:

1. The percent recovery for 4,4'-DDT was outside the 65%-135% project acceptance criteria in QC sample BB1TP106(3.5) MSD at 64%. The non-detected result for 4,4'-DDT in the parent sample was qualified as estimated (UJ).
2. The percent recovery for 4,4'-DDT in QC sample 182560-001 MS was outside the 65%-135% project acceptance criteria at 154%. The parent sample was associated with a site unrelated site to the project site and qualification was not required. QC Batch 106900.

See Table 2 of this report for a summary of qualifications due to matrix spike percent recovery failure.

J. Compound Identification and Quantitation

Samples BBD2TP105(11.5) (179182-001), BBD2TP105(15.0) (179182-002), BBD2TP106(2.0) (179182-003), BBSB119(2.5) (182357-001) and BBSB119(4.5) (182357-002) received full (Level IV) data validation. This included re-calculation of PEM standards, initial and continuing calibrations and surrogate values; in addition to re-calculation of all reported results for pesticides in these samples. The results for pesticides were verified as correctly reported by the laboratory.

VII. Polychlorinated Biphenyls (PCBs) (8082)

Overall, the data are usable as reported with any added qualifiers. Qualification was required for the reason noted in Section F.

A. Reporting Limits

The laboratory reporting limits for PCBs in water and soil matrix samples met the project required reporting limits. It should be noted that the reporting limits for all soils were raised due to dry weight correction.

B. Holding Times

Technical holding time criteria were met for all project samples.

C. Blanks

Target analytes were not observed in any laboratory method blanks associated with the project samples.

D. Initial Calibration

Initial calibration criteria were met for all calibration standards associated with the project samples.

E. Continuing Calibration

Continuing calibration criteria were met for all continuing calibration verification standards associated with the project samples. Qualification was not required for samples with non-detect results associated with high-failing CCV standards. Those failures were not noted in this report.

F. Surrogate Recoveries

Surrogate spike recoveries met QC acceptance criteria for all project samples, with the following exceptions:

1. The percent recovery for surrogate decachlorobiphenyl (DCB) was outside the 65%-135% project acceptance criteria in sample BBIPZ101 at 44%. The PCBs associated with this surrogate, PCB-1248, PCB-1254 and PCB-1260, were non-detect and qualified as estimated (UJ).

2. Samples with non-detect results and high-failing surrogate recoveries did not require qualification, and were not noted in this report.

See Table 2 of this report for a summary of qualifications due to surrogate percent recovery failure.

G. Laboratory Control Samples

All QC criteria were met for the laboratory control samples associated with the project samples.

H. Matrix Spike/Matrix Spike Duplicate

All QC criteria were met for the matrix spike and matrix spike duplicate associated with the project samples.

I. Compound Identification and Quantitation

Samples BBD2TP105(11.5) (179182-001), BBD2TP105(15.0) (179182-002), BBD2TP106(2.0) (179182-003), BBSB119(2.5) (182357-001) and BBSB119(4.5) (182357-002) received full (Level IV) data validation. This included re-calculation of initial and continuing calibrations and surrogate values; in addition to re-calculation of all reported results for PCBs in these samples. The results for PCBs were verified as correctly reported by the laboratory.

VIII. Total and Dissolved Metals (6010B/6020/7470A/7471A)

Overall, the data are usable as reported with any added qualifiers. Qualifications were required for the reasons noted in Sections F and H.

A. Reporting Limits

The laboratory reporting limits for total and dissolved metals in water and soil matrix samples met the project required reporting limits. It should be noted that the reporting limits for all soils were raised due to dry weight correction.

B. Holding Times

Technical holding time criteria were met for all project samples.

C. Blanks

Target analytes were not observed in any laboratory method blanks associated with the project samples, with the following exceptions:

1. Laboratory method blank QC293915 had detected levels of antimony (0.095 mg/kg), cobalt (0.0038 mg/kg), lead (0.012 mg/kg), molybdenum (0.028 mg/kg) and thallium (0.035 mg/kg). The associated samples had levels of cobalt and lead greater than five times the blank amounts, and qualification was not required. The results for antimony, molybdenum and thallium in the associated samples were changed to non-detect (U) if those values were less than five times the blank amount.

2. Laboratory method blank QC293127 had a detected level of molybdenum (0.19 mg/kg). The results for molybdenum in the associated samples were changed to non-detect (U) if those values were less than five times the blank amount.
3. Laboratory method blank QC292252 had detected levels of chromium (0.068 mg/kg), lead (0.02 mg/kg), selenium (0.11 mg/kg) and zinc (0.22 mg/kg). The associated samples had levels of chromium, lead and zinc greater than five times the blank amounts, and qualification was not required. The results for selenium in the associated samples were changed to non-detect (U) if those values were less than five times the blank amount.
4. Laboratory method blank QC294826 had detected levels of arsenic (0.24 mg/kg), lead (0.013 mg/kg), molybdenum (0.012 mg/kg) and thallium (0.017 mg/kg). The associated samples had levels of these metals greater than five times the blank amounts, and qualification was not required.
5. Laboratory method blank QC294960 had a detected level of zinc (0.078 mg/kg). The associated samples had levels of zinc greater than five times the blank amount, and qualification was not required.
6. Laboratory method blank QC313185 had detected levels of chromium (0.063 mg/kg), copper (0.18 mg/kg) and molybdenum (0.030 mg/kg). The associated samples had levels of these metals greater than five times the blank amounts, and qualification was not required.
7. Laboratory method blank QC313706 had detected levels of chromium (0.046 mg/kg), copper (0.066 mg/kg), molybdenum (0.041 mg/kg) and nickel (0.037 mg/kg). The associated samples had levels of these metals greater than five times the blank amounts, and qualification was not required.

See Table 2 of this report for a summary of qualifications due to blank contamination.

D. Initial and Continuing Calibrations

All initial and continuing calibration verification standards associated with the project samples met QC acceptance criteria.

E. Laboratory Control Samples

All QC criteria were met for the laboratory control samples associated with the project samples.

F. Matrix Spike/Matrix Spike Duplicate

All QC criteria were met for the matrix spikes and matrix spike duplicates associated with the project samples, with the following exceptions:

1. The percent recoveries were outside the 75%-125% project acceptance criteria in QC samples BB1ATP101-G2 MS and/or MSD for antimony at 35% and 34%, barium at 66%, copper at 27% and -12%, lead at 71% and 62%, vanadium at 70%, and zinc at 44% and

20%. The detected results for these metals in the associated samples were qualified as estimated with a low bias (J-). QC Batch 101496

2. The percent recoveries were outside the 75%-125% project acceptance criteria in QC samples BBD2TP105 (11.5) MS and/or MSD for antimony at 37% and 34%, barium at 68% and 66%, chromium at 65%, lead at 41% and 18%, nickel at 40%, vanadium at 66% and 48%, and zinc at 49% and 41%. The detected results for these metals in the associated samples were qualified as estimated with a low bias (J-). QC Batch 101627
3. The percent recoveries were outside the 75%-125% project acceptance criteria in QC samples BB1TP106 (6.0) MS and/or MSD for antimony at 31% and 40%, chromium at 48% and -74%, nickel at 60% and -75%, and vanadium at -29%. In addition, the relative percent differences were outside the 30% project acceptance criteria for chromium at 55%, nickel at 58% and vanadium at 53%. The results for these metals in the associated samples were qualified as estimated (J-/UJ) for percent recovery and/or RPD failure. In the same QC samples, the percent recoveries and RPDs were outside the 75%-125% recovery and 30% RPD QC acceptance criteria for barium, lead and zinc. The amounts of these metals present in the parent sample were greater than four times the amounts spiked, and qualification was not required. QC Batch 101858
4. The percent recoveries for mercury in QC samples BB1TP107(7.0) MS/MSD were outside the 75%-125% project acceptance criteria at 62% and 62%, respectively. The detected results for mercury in the associated samples were qualified as estimated with a low bias (J-). QC Batch 101939
5. The percent recoveries for several metals were outside the 75%-125% project acceptance criteria in QC samples BB2ASB100(4.0) MS and/or MSD. The recoveries for antimony were 36% and 38%, barium at -30% and -29%, vanadium at 71%, and zinc at 494%. In addition, the RPD for zinc failed the 30% project acceptance criteria at 92%. The amount of barium in the parent sample was greater than four times the amount spiked, and qualification was not required. The detected results for antimony and vanadium were qualified as estimated with a low bias (J-). The detected results for zinc in the associated samples were qualified as estimated with a high bias (J+) for percent recovery and RPD failure. QC Batch 102065
6. The percent recoveries for several metals were outside the 75%-125% project acceptance criteria in QC samples BBSB101(0.5) MS and/or MSD. The recoveries for antimony were 45% and 47%, barium at 66%, chromium at 166% and 186%, nickel at 127%, vanadium at 142% and zinc at 137% and 132%. The detected results for antimony and barium were qualified as estimated with a low bias (J-). The detected results for chromium, nickel, vanadium and zinc were qualified as estimated with a high bias (J+). QC Batch 102304

7. The percent recoveries for several metals were outside the 75%-125% project acceptance criteria in QC samples BBSB106(0.5) MS and/or MSD. The recoveries were barium at -25% and 56%, chromium at 20%, lead at 65%, nickel at 45%, vanadium at 35%, and zinc at -441% and -334%. The amounts of barium and zinc in the parent sample were greater than four times the amounts spiked, and qualification was not required. The detected results for chromium, nickel, lead and vanadium were qualified as estimated with a low bias (J-). QC Batch 102337
8. The percent recoveries for antimony were outside the 75%-125% project acceptance criteria in QC samples 182483-002 MS/MSD. The parent sample was associated with a site unrelated to the project site and qualification was not required QC Batch 106787
9. The percent recoveries for antimony were outside the 75%-125% project acceptance criteria in QC samples BBSB119(4.5) MS/MSD at 44% and 41%. The detected results for antimony were qualified as estimated with a low bias (J-). QC Batch 106917

See Table 2 of this report for a summary of qualifications due to matrix spike percent recovery and RPD failures.

G. ICP Interference Check Standards

All QC criteria were met for the ICP interference check standards associated with the project samples.

H. ICP Serial Dilution

ICP serial dilutions met method requirements with the following exceptions:

1. The percent difference failed the 10% difference project acceptance criteria for molybdenum in the serial dilution of sample BB2ASB100(4.0) at 22%. The results for molybdenum in the associated samples were qualified as estimated (J). QC Batch 102065
2. The percent differences failed the 10% difference project acceptance criteria for molybdenum at 20% and zinc at 24% in the serial dilution of sample BB2TP105(11.5). The results for molybdenum and zinc in the associated samples were qualified as estimated (J/UJ). QC Batch 101627
3. The percent difference failed the 10% difference project acceptance criteria for molybdenum in the serial dilution of sample BB1TP106(6.0) at 47%. The results for molybdenum in the associated samples were qualified as estimated (J). QC Batch 101858
4. The percent difference failed the 10% difference project acceptance criteria for vanadium in the serial dilution of sample BB1SB101(0.5) at 13%. The results for vanadium in the associated samples were qualified as estimated (J). QC Batch 102304
5. The percent difference failed the 10% difference project acceptance criteria for molybdenum in the serial dilution of sample BBSB106(0.5)

at 96%. The results for molybdenum in the associated samples were qualified as estimated (J). QC Batch 102337

6. The percent difference failed the 10% difference project acceptance criteria for zinc in the serial dilution of sample BB1PZ101 at 27%. The results for total and dissolved zinc in the associated sample were qualified as estimated (J). QC Batch 104577

See Table 2 of this report for a summary of qualifications due to serial dilution failure.

I. Compound Identification and Quantitation

Samples BBD2TP105(11.5) (179182-001), BBD2TP105(15.0) (179182-002), BBD2TP106(2.0) (179182-003), BBSB119(2.5) (182357-001) and BBSB119(4.5) (182357-002) received full (Level IV) data validation. This included re-calculation of initial and continuing calibrations; in addition to re-calculation of all reported results for metals in these samples. The results for metals were verified as correctly reported by the laboratory.

The following paragraphs highlight the essential findings of the field duplicate samples:

Field duplicate precision was evaluated by calculating the relative percent difference (RPD) between detected results in the original sample and its associated duplicate. The control limit used for field duplicates was a relative percent difference less than or equal to 50 percent, or the absolute difference of the two results must be less than twice the reporting limit for those analytes that were at or near the detection limit. Two samples were collected in duplicate for the Baker Beach sampling event.

Project Sample Primary ID	Laboratory Sample ID	Project Sample Duplicate ID	Laboratory Sample ID
BBSB109(0.0)	179445-006	DUP(050512)	179445-007
BB1TP106(2.5)	179266-003	DUP(050405)	179266-004

The attached Table 3 summarizes the field duplicate sample results. The detected results of the original sample and the associated duplicate sample were compared and the calculated relative percent differences (RPDs) reported.

All RPDs met the 50 percent precision control limit requirement (or +/- two times the reporting limit for values at or near the detection limit), with the following exceptions:

1. In field duplicates BB1TP106(2.5) and DUP(050405), the relative percent differences failed for chromium at 148%, cobalt at 104%, nickel at 155%, barium at 76%, beryllium at 74%, copper at 90%, lead at 149%, mercury at 157%, diesel at 196%, fuel oil at 193%, dieldrin at 200%, 4,4'-DDE at 200%, 4,4'-DDD at 200%, 4,4'-DDT at 200%, alpha-chlordane at 200%, phenanthrene at 200%, fluoranthene at 200%, pyrene at 200%, benzo(a)anthracene at 200%, chrysene at 200%, benzo(b)fluoranthene at 200%, benzo(k)fluoranthene at 187% and benzo(a)pyrene at 200%.
2. In field duplicates BBSB109(0.0) and DUP(050512), the relative percent differences failed for lead at 165%, chromium at 55%, molybdenum at 123%, nickel at 59%, mercury at 68%, para-isopropyl toluene at 200%, phenanthrene at 91%, fluoranthene at 96%, pyrene at 89%, benzo(a)anthracene at 102%, chrysene at 96%, benzo(b)fluoranthene at 107%, benzo(k)fluoranthene at 89%, benzo(a)pyrene at 109%, indeno(1,2,3cd)pyrene at 62% and benzo(g,h,i)perylene at 72%.

The analysis of field duplicate samples is a measure of both field and analytical precision. The imprecision in the results in the field duplicate pairs listed above may be due to the sample matrix, sampling or laboratory technique, sample non-homogeneity, or method defects. With the exceptions noted above, the results between the field duplicate pairs matched well. Since the effect on the quality of the data is not known, data is not qualified for field duplicate failure.

SUMMARY

The attached Table 1 summarizes the site samples, laboratory sample IDs, sampling dates, analysis methods and sample types. The attached Table 2 summarizes the data qualifications of all project samples for each test method included in the data package.

USABILITY

The quality control criteria were reviewed, and other than those discussed above, all criteria were met and the data are considered acceptable. Estimated sample results (J/UJ) are usable only for limited purposes. Rejected sample results are not usable for any purpose. Based upon the full and cursory validation, all other results are considered valid and usable for all purposes.

VALIDATION QUALIFIERS IDENTIFICATION

The definitions of the following qualifiers are prepared according to the document, "USEPA Contract Laboratory Program National Functional Guidelines for Organic Data Review," October, 1999.

U The analyte was analyzed for, but was not detected above the reported sample quantitation limit.

J The analyte was positively identified; the associated numerical value is the approximate concentration of the analyte in the sample. *A minus sign (-) indicates the numerical value has a low bias. A plus sign (+) indicates the numerical value has a high bias.*

N The analysis indicates the presence of an analyte for which there is presumptive evidence to make a "tentative identification."

NJ The analysis indicates the presence of an analyte that has been "tentatively identified" and the associated numerical value represents its approximate concentration.

UJ The analyte was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the actual limit of quantitation necessary to accurately and precisely measure the analyte in the sample.

R The sample results are rejected due to serious deficiencies in the ability to analyze the sample and meet quality control criteria. The presence or absence of the analyte cannot be verified.

Table 1
Summary of Samples/Analyses
Baker Beach
The Presidio of San Francisco, CA

Site Sample ID	Laboratory Sample ID	Date Sampled	Analyses	Sample Type
BB1ATP101-G1	178846-001	7-Apr-05	PAHs (8270C-SIM), Total Metals (6020/7471A)	Soil
BB1ATP101-G2	178846-002	7-Apr-05	PAHs (8270C-SIM), Total Metals (6020/7471A)	Soil
BB2ATP104(8.0)	178951-001	13-Apr-05	VOCs (8260B), PAHs (8270C-SIM), TPH-Gasoline (8015B), TPH-Diesel/Fuel Oil (8015B), PCBs (8082), Total Metals (6020/7471A)	Soil

NC: Not calculated. The absolute difference between the sample result and the duplicate sample result is less than the reporting limit.

ND: The sample result was non-detect.

N/A: Not analyzed

NA: Not applicable. Calculation of the relative percent difference between the sample result and the duplicate sample result is not applicable.

Units: mg/kg for TPH-Gasoline, TPH-diesel, and metals
ug/kg for VOCs, Pesticides,PCBs, and PAHs

DATA VALIDATION SUMMARY REPORT FOR THE BAKER BEACH SITE, THE PRESIDIO OF SAN FRANCISCO, CA

LABORATORY: Curtis & Tompkins Laboratories, Berkeley, CA

SAMPLING DATE: February 1, 2006

Data validation of Level III and Level IV laboratory data packages was performed according to the project-specific guidelines. These guidelines were outlined in the Presidio-wide Quality Assurance Project Plan, Sampling and Analysis Plan, April, 2001; the U. S. Environmental Protection Agency Contract Laboratory Program National Functional Guidelines for Organic Data Review, October, 1999; and the U. S. Environmental Protection Agency Contract Laboratory Program National Functional Guidelines for Inorganic Data Review, October, 2004.

The data were reviewed for holding times, blanks, GC/MS tunes, initial calibrations, continuing calibration verification (CCV) standards, performance evaluation mix (PEM) standards, surrogate recoveries, internal standards, laboratory control samples (LCS), laboratory duplicate samples, matrix spikes (MS), matrix spike duplicates (MSD), ICP interference check standards, ICP serial dilutions, field QC blanks, field duplicate samples and compound identification and quantitation.

The following paragraphs highlight the essential findings of the data validation effort:

I. **Volatile Organic Compounds by GC/MS (8260B)**

Overall, the data are usable as reported with any added qualifiers. Qualifications were required for the reasons noted in Sections C and F.

A. Reporting Limits

The laboratory reporting limits for VOCs in water matrix samples met the project required reporting limits, with the following exceptions:

1. The following table lists the compounds for which the laboratory reporting limits did not meet the project required reporting limits listed in Table 2-6.8-1 of the QAPP.

Compound	Matrix	Laboratory Reporting Limit	Project Required Reporting Limit
Bromoform	Water	1.0 ug/L	0.5 ug/L
Bromomethane	Water	1.0 ug/L	0.5 ug/L

Reviewed: MJ It

Compound	Matrix	Laboratory Reporting Limit	Project Required Reporting Limit
Chloroethane	Water	1.0 ug/L	0.5 ug/L
Chloromethane	Water	1.0 ug/L	0.5 ug/L
Methylene chloride	Water	10 ug/L	4.5 ug/L

B. Holding Times

Technical holding time criteria specified in the analysis method were met for all project samples.

C. Blanks

Target analytes were not observed in any laboratory method blanks or trip blanks associated with the project samples, with the following exceptions:

1. Laboratory method blank QC326953 had a detected level of methylene chloride at 0.3 ug/L. The detected results for methylene chloride in the associated project samples were changed to non-detect (U) if those values were less than ten times the blank amount.
2. Trip blank TB (020106) (184692-004) had a detected level of methylene chloride at 0.2 ug/L. The detected results for methylene chloride in the associated project samples were changed to non-detect (U) if those values were less than ten times the blank amount. It should be noted that the methylene chloride result for trip blank sample TB (020106) (184692-004) was previously changed to non-detect (U) due to method blank contamination.

See Table 2 of this report for a summary of qualifications due to blank contamination.

D. GC/MS Tunes

All QC criteria were met for the GC/MS tunes associated with the project samples.

E. Initial Calibration

Initial calibration criteria were met for all initial calibration standards associated with the project samples.

F. Continuing Calibration

Continuing calibration criteria were met for all continuing calibration verification (CCV) standards associated with the project samples, with the following exception:

1. The 2/6/06 at 09:18 water matrix CCV analyzed on instrument MSVOA05 had four compounds with percent differences less than -25%: chloromethane (-28%), 2-butanone (-30%), 1,2-dibromo-3-chloropropane (-26%) and naphthalene (-47%). The associated samples were non-detect for these compounds and qualified as estimated (UJ).

See Table 2 of this report for a summary of qualifications due to continuing calibration percent difference failure.

G. Internal Standards
Internal standard QC acceptance criteria were met for all project samples.

H. Surrogate Recoveries
Surrogate spike recoveries met QC acceptance criteria for all project samples.

I. Laboratory Control Samples
All QC criteria were met for the laboratory control samples associated with the project samples.

J. Matrix Spike/Matrix Spike Duplicate
All QC criteria were met for the matrix spikes and matrix spike duplicates associated with the project samples.

K. Compound Identification and Quantitation
Samples BB2ASW100 (184691-001), BB1PZ100 (184692-001), DUP (020106) (184692-002), BB1PZ101 (184692-003) and TB (020106) (184692-004) received full (Level IV) data validation. This included re-calculation of initial and continuing calibrations and surrogate values; in addition to re-calculation of all reported results for VOCs in these samples. The results for VOCs were verified as correctly reported by the laboratory.

II. Polynuclear Aromatic Hydrocarbons (PAHs) by GC/MS (8270C-SIM)

Overall, the data are usable as reported with any added qualifiers. Qualifications were required for the reasons noted in Sections C, G and J.

A. Reporting Limits
The laboratory reporting limits for PAHs in soil and water matrix samples met the project required reporting limits. It should be noted that the reporting limits for all soils were raised due to dry weight correction.

B. Holding Times
Technical holding time criteria were met for all project samples.

C. Blanks

Target analytes were not observed in any laboratory method blanks associated with the project samples, with the following exception:

1. Laboratory method blank QC326884 had a detected level of pyrene at 0.01 ug/L. The detected results for pyrene in the associated samples were changed to non-detect (U) if those values were less than five times the blank amount.

See Table 2 of this report for a summary of qualifications due to blank contamination.

D. GC/MS Tunes

All QC criteria were met for the GC/MS tunes associated with the project samples.

E. Initial Calibration

Initial calibration criteria were met for all calibration standards associated with the project samples.

F. Continuing Calibration

Continuing calibration criteria were met for all continuing calibration verification standards associated with the project samples.

G. Internal Standards

Internal standard QC acceptance criteria were met for all project samples with the following exception:

1. The area count for internal standard perylene-d12 was outside the -50% to +100% acceptance criteria in project sample BBSB120(1.0) (184679-001). The compounds associated with this internal standard were qualified as estimated (J/UJ).

See Table 2 of this report for a summary of qualifications due to internal standard area count failure.

H. Surrogate Recoveries

Surrogate spike recoveries met QC acceptance criteria for all project samples, with the following exception:

1. Samples with one failing acid surrogate and/or one failing base/neutral surrogate did not require qualification. Those failures were not noted in this report.

I. Laboratory Control Samples

All QC criteria were met for the laboratory control samples associated with the project samples.

J. Matrix Spike/Matrix Spike Duplicate

All QC criteria were met for the matrix spikes and matrix spike duplicates associated with the project samples, with the following exception:

1. The percent recoveries for pyrene were outside the 35% - 142% project acceptance criteria in QC samples BBSB120(1.0) (184679-001) MS/MSD. The amount of pyrene present in the parent sample was greater than four times the amount spiked, and qualification was not required. In the same QC samples, the relative percent difference (RPD) was outside the 21% QC acceptance criteria for acenaphthene at 68%. The detected result for acenaphthene in the sample was qualified as estimated (J). QC Batch 110148.

See Table 2 of this report for a summary of qualifications due to matrix spike RPD failure.

K. Compound Identification and Quantitation

Samples BB2ASW100 (184691-001), BB1PZ100 (184692-001), DUP (020106) (184692-002) and BB1PZ101 (184692-003) received full (Level IV) data validation. This included re-calculation of GC/MS tunes, initial and continuing calibrations, surrogate values, and internal standard areas; in addition to re-calculation of all reported results for PAHs in these samples. The results for PAHs were verified as correctly reported by the laboratory.

III. Total Petroleum Hydrocarbons - Gasoline Range (8015B)

Overall, the data are usable as reported with any added qualifiers. Qualifications were required for the reasons noted in Section C.

A. Reporting Limits

The laboratory reporting limit for TPH-gasoline in water matrix samples met the project required reporting limit.

B. Holding Times

Technical holding time criteria were met for all project samples.

C. Blanks

Target analytes were not observed in any laboratory method blanks or trip blanks associated with the project samples, with the following exceptions:

1. Laboratory method blank QC326759 had a detected level of TPH-gasoline at 18 ug/L. The detected results for TPH-gasoline in the associated project samples were changed to non-detect (U) if those values were less than five times the blank amount.

2. Trip blank TB (020106) (184692-004) had a detected level of TPH-gasoline at 25 ug/L. The detected results for TPH-gasoline in the associated project samples were changed to non-detect (U) if those values were less than five times the blank amount. It should be noted that the TPH-gasoline result for trip blank sample TB (020106) (184692-004) was previously changed to non-detect (U) due to method blank contamination.

See Table 2 of this report for a summary of qualifications due to blank contamination.

D. Initial Calibration
Initial calibration criteria were met for all calibration standards associated with the project samples.

E. Continuing Calibration
Continuing calibration criteria were met for all continuing calibration verification standards associated with the project samples.

F. Surrogate Recoveries
Surrogate spike recoveries met QC acceptance criteria for all project samples.

G. Laboratory Control Samples
All QC criteria were met for the laboratory control samples associated with the project samples.

H. Matrix Spike/Matrix Spike Duplicate
All QC criteria were met for the matrix spikes and matrix spike duplicates associated with the project samples.

I. Compound Identification and Quantitation
Samples BB2ASW100 (184691-001), BB1PZ100 (184692-001), DUP (020106) (184692-002), BB1PZ101 (184692-003) and TB (020106) (184692-004) received full (Level IV) data validation. This included re-calculation of initial and continuing calibrations, and surrogate values; in addition to re-calculation of the reported results for TPH-gasoline in these samples. The results for TPH-gasoline were verified as correctly reported by the laboratory.

IV. Total Petroleum Hydrocarbons – Diesel/Fuel Oil (8015B)

Overall, the data are usable as reported. Qualification was not required.

A. Reporting Limits
The laboratory reporting limits for TPH-diesel and TPH-fuel oil in water matrix samples met the project required reporting limits.

B. Holding Times
Technical holding time criteria were met for all project samples.

C. Blanks
Target analytes were not observed in any laboratory method blanks associated with the project samples.

D. Initial Calibration
Initial calibration criteria were met for all calibration standards associated with the project samples.

E. Continuing Calibration
Continuing calibration criteria were met for all continuing calibration verification standards associated with the project samples.

F. Surrogate Recoveries
Surrogate spike recoveries met QC acceptance criteria for all project samples.

G. Laboratory Control Samples
All QC criteria were met for the laboratory control samples associated with the project samples.

H. Matrix Spike/Matrix Spike Duplicate
All QC criteria were met for the matrix spikes and matrix spike duplicates associated with the project samples.

I. Compound Identification and Quantitation
Samples BB2ASW100 (184691-001), BB1PZ100 (184692-001), DUP (020106) (184692-002) and BB1PZ101 (184692-003) received full (Level IV) data validation. This included re-calculation of initial and continuing calibrations, and surrogate values; in addition to re-calculation of the reported results for TPH-diesel and TPH-fuel oil in these samples. The results for TPH-diesel and TPH-fuel oil were verified as correctly reported by the laboratory.

V. Organochlorine Pesticides (8081A)

Overall, the data are usable as reported. Qualification was not required.

A. Reporting Limits
The laboratory reporting limits for pesticides in water matrix samples met the project required reporting limits.

B. Holding Times
Technical holding time criteria were met for all project samples.

C. Blanks
Target analytes were not observed in any laboratory method blanks associated with the project samples.

D. Initial Calibration
Initial calibration criteria were met for all calibration standards associated with the project samples with the following exception:
1. Data was obtained from two columns, and calibration standards with percent relative standard deviation (%RSDs) that failed criteria on one column did not require qualification if sample results were reported from the column in control. Those failures were not noted in this report.

E. Continuing Calibration
Continuing calibration criteria were met for all continuing calibration verification standards associated with the project samples with the following exceptions:
1. Qualification was not required for samples with non-detect results associated with high-failing CCVs. Those failures were not noted in this report.
2. Data was reported from two columns, and CCVs with percent differences that failed criteria on one column did not require qualification if sample results were reported from the column in control. Those failures were not noted in this report.

F. Performance Evaluation Mix (PEM) Check Standards
All PEM check standards met the project degradation criteria of 15% for endrin and 4,4'-DDT.

G. Surrogate Recoveries
Surrogate spike recoveries met QC acceptance criteria for all project samples.

H. Laboratory Control Samples
All QC criteria were met for the laboratory control samples associated with the project samples.

I. Matrix Spike/Matrix Spike Duplicate
All QC criteria were met for the matrix spike and matrix spike duplicates associated with the project samples.

J. Compound Identification and Quantitation
Samples BB2ASW100 (184691-001), BB1PZ100 (184692-001), DUP (020106) (184692-002) and BB1PZ101 (184692-003) received full (Level IV) data validation. This included re-calculation of PEM standards, initial and continuing calibrations and surrogate values; in addition to re-

calculation of all reported results for pesticides in these samples. The results for pesticides were verified as correctly reported by the laboratory.

VI. Polychlorinated Biphenyls (PCBs) (8082)

Overall, the data are usable as reported with any added qualifiers. Qualification was required for the reason noted in Section F.

A. Reporting Limits

The laboratory reporting limits for PCBs in water matrix samples met the project required reporting limits.

B. Holding Times

Technical holding time criteria were met for all project samples.

C. Blanks

Target analytes were not observed in any laboratory method blanks associated with the project samples.

D. Initial Calibration

Initial calibration criteria were met for all calibration standards associated with the project samples.

E. Continuing Calibration

Continuing calibration criteria were met for all continuing calibration verification standards associated with the project samples with the following exceptions:

1. Qualification was not required for samples with non-detect results associated with CCVs that failed high. Those failures were not noted in this report.
2. Data was reported from two columns, and CCVs with percent differences that failed criteria on one column did not require qualification if sample results were reported from the column in control. Those failures were not noted in this report.

F. Surrogate Recoveries

Surrogate spike recoveries met QC acceptance criteria for all project samples, with the following exception:

1. The percent recoveries for surrogate decachlorobiphenyl (DCB) were outside the 65%-135% project acceptance criteria in samples BB2ASW100 (184691-001) (44%), BB1PZ100 (184692-001) (45%) and DUP(020106) (184692-002) (40%). The PCBs associated with this surrogate, PCB-1248, PCB-1254 and PCB-1260, were non-detect and qualified as estimated (UJ).

See Table 2 of this report for a summary of qualifications due to surrogate percent recovery failure.

G. Laboratory Control Samples
All QC criteria were met for the laboratory control samples associated with the project samples.

H. Matrix Spike/Matrix Spike Duplicate
All QC criteria were met for the matrix spike and matrix spike duplicate associated with the project samples.

I. Compound Identification and Quantitation
Samples BB2ASW100 (184691-001), BB1PZ100 (184692-001), DUP (020106) (184692-002) and BB1PZ101 (184692-003) received full (Level IV) data validation. This included re-calculation of initial and continuing calibrations and surrogate values; in addition to re-calculation of all reported results for PCBs in these samples. The results for PCBs were verified as correctly reported by the laboratory.

VII. Total and Dissolved Metals (6010B/6020/7470A/7471A)

Overall, the data are usable as reported with any added qualifiers. Qualifications were required for the reasons noted in Sections B, C, F and H.

A. Reporting Limits
The laboratory reporting limits for total and dissolved metals in water and soil matrix samples met the project required reporting limits. It should be noted that the reporting limits for all soils were raised due to dry weight correction.

B. Holding Times
Technical holding time criteria were met for all project samples, with the following exception:
1. Sample BB2SB110(1.0) (185213-001) was analyzed for mercury 6 days past the 28 day analysis holding time. The detected result for mercury in the sample was qualified as estimated with a low bias (J-).

See Table 2 of this report for a summary of qualifications due to missed analysis holding time.

C. Blanks
Target analytes were not observed in any laboratory method blanks or calibration blanks associated with the project samples, with the following exceptions:
1. Laboratory method blank QC326681 had a detected level of chromium at 0.050 mg/kg. The associated samples had levels of chromium greater than five times the blank amount, and qualification was not required.
2. Laboratory method blank QC326688 had detected levels of chromium (0.043 mg/kg), nickel (0.038 mg/kg) and thallium (0.047 mg/kg). The associated samples were non-detect for thallium and had levels of

chromium and nickel greater than five times the blank amounts, and qualification was not required.

3. Laboratory method blank QC326963 had a detected level of molybdenum at 0.28 ug/L. The associated samples had levels of molybdenum greater than five times the blank amount, and qualification was not required.
4. Laboratory method blank QC327072 had a detected level of chromium at 0.042 mg/kg. The associated samples had levels of chromium greater than five times the blank amount, and qualification was not required.
5. The second continuing calibration blank analyzed on 2/22/06 on instrument MET05 had a detected level of lead at 0.326 ug/L. The results for lead in the associated samples were changed to non-detect (U) if those values were less than five times the blank amount.
6. The third continuing calibration blank analyzed on 2/22/06 on instrument MET05 had detected levels of chromium (0.155 ug/L) and cobalt (0.042 ug/L). The associated samples had levels of chromium greater than five times the blank amount, and qualification was not required. The results for cobalt in the associated samples were changed to non-detect (U) if those values were less than five times the blank amount.
7. Laboratory method blank QC329855 had detected levels of chromium (0.053 mg/kg), copper (0.064 mg/kg) and nickel (0.045 mg/kg). The associated samples had levels of chromium, copper and nickel greater than five times the blank amounts, and qualification was not required.
8. Laboratory method blank QC330027 had detected levels of chromium (0.061 mg/kg), copper (0.28 mg/kg), molybdenum (0.029 mg/kg) and thallium (0.037 mg/kg). The associated samples had levels of chromium, copper and molybdenum greater than five times the blank amounts, and qualification was not required. The results for thallium in the associated samples were changed to non-detect (U) if those values were less than five times the blank amount.

See Table 2 of this report for a summary of qualifications due to blank contamination.

D. Initial and Continuing Calibrations

All initial and continuing calibration verification standards associated with the project samples met QC acceptance criteria.

E. Laboratory Control Samples

All QC criteria were met for the laboratory control samples associated with the project samples.

F. Matrix Spike/Matrix Spike Duplicate

All QC criteria were met for the matrix spikes and matrix spike duplicates associated with the project samples, with the following exceptions:

1. The percent recoveries were outside the 75%-125% project acceptance criteria in QC samples BB2SB110(0.5) (184678-001) MS/MSD for antimony (22%/23%), chromium (-94%/-100%), nickel (-566%/-600%) and silver (58%/63%). The amounts of chromium and nickel present in the parent sample were greater than four times the amounts spiked, and qualification was not required. The non-detected results for silver in the associated samples were qualified as estimated (UJ). The percent recoveries for antimony were less than 30%, which required rejection of non-detected results. The detected results for antimony in the associated samples were qualified as estimated with a low bias (J-); the non-detected results for antimony in the associated samples were qualified as rejected (R). (QC batch 110124)
2. The percent recoveries were outside the 75%-125% project acceptance criteria in QC samples BBSB120(1.0) (184679-001) MS/MSD for antimony (36%/31%), nickel (42%/66%) and silver (69%/60%). The amount of nickel present in the parent sample was greater than four times the amount spiked, and qualification was not required. The results for antimony and silver in the associated sample were qualified as estimated with a low bias (J-/UJ). (QC batch 110211)
3. The percent recoveries were outside the 75%-125% project acceptance criteria in QC samples BB1SB115(0.5) (184680-001) MS and/or MSD for antimony (26%/29%), arsenic (70%), barium (238%/71%), cobalt (169%), copper (-617%/-325%), lead (47%), nickel (173%), silver (67%/36%), thallium (73%), vanadium (62%) and zinc (-348%/-216%). In addition, the relative percent differences were outside the 30% project acceptance criteria for barium (52%), cobalt (39%) and silver (59%). The amounts of copper, nickel and zinc present in the parent sample were greater than four times the amounts spiked, and qualification was not required. The detected results for antimony, arsenic, lead, thallium and vanadium in the associated sample were qualified as estimated with a low bias (J-). The detected result for cobalt in the associated sample was qualified as estimated with a high bias (J+) for percent recovery and RPD failure. The results for barium and silver in the associated sample were qualified as estimated with a low bias (J-/UJ) for percent recovery and RPD failure. (QC Batch 110123)
4. The percent recoveries were outside the 75%-125% project acceptance criteria in QC samples BB2ASW100 (184691-001) MS and/or MSD for barium (135%/129%), chromium (62%/60%), copper (73%), lead (128%), nickel (-69%/-68%) and zinc (16%/29%). The amounts of lead, nickel and zinc present in the parent sample were greater than four times the amounts spiked, and qualification was not required. The detected results for barium in the associated samples

were qualified as estimated with a high bias (J+). The detected results for chromium and copper in the associated samples were qualified as estimated with a low bias (J-). (QC batch 110189)

5. The percent recoveries were outside the 75%-125% project acceptance criteria in QC samples BB2SB110(1.0) (185213-001) MS and/or MSD for antimony (24%/23%), chromium (335%), cobalt (70%), nickel (389%/-160%) and silver (58%/58%). The amounts of chromium and nickel present in the parent sample were greater than four times the amounts spiked, and qualification was not required. The detected result for antimony in the associated sample was qualified as estimated with a low bias (J-). The results for cobalt and silver in the associated samples were qualified as estimated with a low bias (J-/UJ). (QC batch 110952)
6. The percent recoveries for antimony, copper and silver failed the 75%-125% acceptance criteria in QC samples 184995-005 MS and/or MSD. The parent sample was associated with a site unrelated to the project site, and qualification of the project samples was not required. (QC batch 110908)

See Table 2 of this report for a summary of qualifications due to matrix spike percent recovery failure.

G. ICP Interference Check Standards

All QC criteria were met for the ICP interference check standards associated with the project samples.

H. ICP Serial Dilution

ICP serial dilutions met the 10% difference method requirement with the following exceptions:

1. The percent difference failed the 10% difference project acceptance criteria for copper in the serial dilution of sample BB2ASW100 (184691-001) at 12%. The results for copper in the associated samples were qualified as estimated (J/UJ). (QC Batch 110189)
2. The percent differences failed the 10% difference project acceptance criteria for cobalt, copper and nickel in the serial dilution of sample 184995-005. The parent sample was associated with a site unrelated to the project site, and qualification of the project samples was not required. (QC Batch 110908)

See Table 2 of this report for a summary of qualifications due to serial dilution failure.

I. Compound Identification and Quantitation

Samples BB2ASW100 (184691-001), BB1PZ100 (184692-001), DUP (020106) (184692-002) and BB1PZ101 (184692-003) received full (Level IV) data validation. This included re-calculation of initial and continuing calibrations; in addition to re-calculation of all reported results for metals in these samples. The results for total and dissolved metals were verified as correctly reported by the laboratory.

VIII. General Chemistry Methods (160.1, 300.1, 310.0, 353.3)

Overall, the data are usable as reported. Qualification was not required.

A. Reporting Limits

The laboratory reporting limits for the general chemistry methods analyzed met the project required reporting limits listed in the tables of the QAPP, with the following exceptions:

1. The laboratory reporting limit for total dissolved solids was 10 mg/L; the project required reporting limit for this analyte was 5 mg/L. The laboratory reporting limit for nitrate+nitrite as nitrogen was 0.1 mg/L, the project required reporting limit for this analyte was 0.05 mg/L.

B. Holding Times

Technical holding time criteria were met for all project samples.

C. Blanks

Target analytes were not observed in any laboratory method blanks associated with the project samples.

D. Laboratory Control Samples

All QC criteria were met for the laboratory control samples associated with the project samples.

E. Matrix Spike/Matrix Spike Duplicate

All QC criteria were met for the matrix spikes and matrix spike duplicates associated with the project samples, with the following exception:

1. The percent recoveries for nitrate+nitrite as nitrogen failed the 80%-120% acceptance criteria in QC samples 06-02-0215-02 MS/MSD. The parent sample was associated with a site unrelated to the project site, and qualification of the project samples was not required. (QC batch 60207N03S1)

F. Laboratory Duplicate Samples

All QC criteria were met for the laboratory duplicate samples associated with the project samples.

G. Initial and Continuing Calibrations

All initial and continuing calibration standards associated with the project samples met QC acceptance criteria.

H. Compound Identification and Quantitation

Samples BB2ASW100 (184691-001), BB1PZ100 (184692-001), DUP (020106) (184692-002) and BB1PZ101 (184692-003) received full (Level IV) data validation. This included re-calculation of initial and continuing calibrations; in addition to re-calculation of all reported results for general chemistry methods in these samples. The results for general chemistry were verified as correctly reported by the laboratory.

SUMMARY

The attached Table 1 summarizes the site samples, laboratory sample IDs, sampling dates, analysis methods and sample types. This table also designates which samples received Level IV data validation. The attached Table 2 summarizes the data qualifications of all project samples for each test method included in the data package.

USABILITY

The quality control criteria were reviewed, and other than those discussed above, all criteria were met and the data are considered acceptable. Estimated sample results (J/UJ) are usable only for limited purposes. Rejected sample results were not usable for any purpose. Based upon the full and cursory validation, all other results are considered valid and usable for all purposes.

VALIDATION QUALIFIERS IDENTIFICATION

The definitions of the following qualifiers are prepared according to the document, "USEPA Contract Laboratory Program National Functional Guidelines for Organic Data Review," October, 1999.

U The analyte was analyzed for, but was not detected above the reported sample quantitation limit.

J The analyte was positively identified; the associated numerical value is the approximate concentration of the analyte in the sample. *A minus sign (-) indicates the numerical value has a low bias. A plus sign (+) indicates the numerical value has a high bias.*

N The analysis indicates the presence of an analyte for which there is presumptive evidence to make a "tentative identification."

NJ The analysis indicates the presence of an analyte that has been "tentatively identified" and the associated numerical value represents its approximate concentration.

UJ The analyte was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the actual limit of quantitation necessary to accurately and precisely measure the analyte in the sample.

R The sample results are rejected due to serious deficiencies in the ability to analyze the sample and meet quality control criteria. The presence or absence of the analyte cannot be verified.

The following paragraphs highlight the essential findings of the field duplicate samples:

Field duplicate precision was evaluated by calculating the relative percent difference (RPD) between detected results in the original sample and its associated duplicate. The control limit used for field duplicates was a relative percent difference less than or equal to 50 percent, or the absolute difference of the two results must be less than the reporting limit (for waters) or less than twice the reporting limit (for soils) for those analytes that were at or near the detection limit. Two samples were collected in duplicate for this Baker Beach sampling event.

Project Sample Primary ID	Laboratory Sample ID	Project Sample Duplicate ID	Laboratory Sample ID
BB2SB110 (0.5)	184678-001	DUP (020106)	184678-002
BB1PZ100	184692-001	DUP (020106)	184692-002

The attached Table 3 summarizes the field duplicate sample results. The detected results of the original sample and the associated duplicate sample were compared and the calculated relative percent differences (RPDs) reported. All RPDs met the 50 percent precision control limit requirement, with the following exceptions:

1. In field duplicates BB2SB110(0.5) (184678-001) and DUP(020106) (184678-002), the relative percent differences failed for chromium (67%) and nickel (51%).
2. In field duplicates BB1PZ100 (184692-001) and DUP(020106) (184692-002), the relative percent differences failed for TPH-diesel (74%), TPH-fuel oil (64%), total chromium (56%), total copper (88%), total molybdenum (71%), dissolved antimony (66%), dissolved arsenic (93%), dissolved cobalt (156%), dissolved molybdenum (114%) and dissolved vanadium (82%).

The analysis of field duplicate samples is a measure of both field and analytical precision. The imprecision in the results in the field duplicate pairs listed above may be due to the sample matrix, sampling or laboratory technique, sample non-homogeneity, or method defects. With the exceptions noted above, the results between the field duplicate pairs matched well. Since the effect on the quality of the data is not known, data is not qualified for field duplicate failure.

NC: Not calculated. The absolute difference between the sample result and the duplicate sample result is less than the reporting limit.
ND: The sample result was non-detect.
N/A: Not analyzed
NA: Not applicable. Calculation of the relative percent difference between the sample result and the duplicate sample result is not applicable.
RPD: Relative percent difference
Units: ug/kg for soil PAHs; mg/kg for soil metals
ug/L for water organics and metals; mg/L for general chemistry analyses

APPENDIX D

GEOTECHNICAL SLOPE STABILITY ANALYSIS

APPENDIX D - SLOPE STABILITY NARRATIVE

Purpose of Slope Stability Analyses:

This appendix presents the results of slope stability analyses we performed to evaluate the coastal bluffs in the vicinity of Baker Beach Disturbed Areas 1, 1A, 2, and 2A. The purpose of the analyses was to assess the stability of the steep bluff slopes under existing conditions, during removal of waste fills, and after remedial actions at the site.

Material Properties:

The stability of the existing and planned slopes was evaluated using soil and rock profiles and material properties as described in the Material Properties Technical Memorandum (*MACTEC, 2005i*). Engineering properties of the fill materials, landslide debris, native soils/Colma Formation, and Franciscan bedrock were based on the results of our field investigation, laboratory testing, and engineering judgment. The soil strength parameters used in the stability analyses (including cohesion, internal angle of friction, and moist unit weight) are presented in Table 15.

Geometric Properties:

Eight subsurface profiles (A-A' through H-H') were selected for the stability analyses. The depths of soil layers and depth to bedrock within each subsurface profile was estimated and interpolated from our exploratory borings and test pits completed during our field investigation. The profiles are located as shown on Plate 2 and are presented in the cross-sections on Plates 5 through 8. The locations of the cross-sections were selected to model the steepest sections of each BBDA and to utilize the maximum amount of available subsurface information. The locations of the cross sections were also selected for stability analyses of the batteries, potential equipment and staging areas, and disturbed areas present near the base of the slopes.

Circular Failure Surface Analyses:

The computer program Slope/W (Version 2004) by Geoslope International (*2004*) was used for the evaluation of non-planar failure surfaces (Spencer's Method) in soils/rocks with cohesion. Three phases are used by the program to perform the stability analyses: 1) the Define phase, 2) the Solve phase, and 3) the Contour phase. Soil strength parameters and geometric slope properties for each slope condition were input into the Define phase of the program. In several cases, line loads were added to model construction equipment and soil stockpile loads at the slope bluff.

During the Solve phase, the most critical slope surfaces are evaluated. For circular failure surfaces, a grid and radius method of analysis is used. The grid consists of circular slip surface centers (circle axis) positioned over the critical slope area. Tangent lines are then inserted parallel to the critical slope face at various depth intervals. Each circle axis point is then evaluated with a circular slip surface that intersects each of the tangent lines. Slope/W uses limit equilibrium theory to compute the factor of safety (ratio of resisting forces to driving forces) for each of the circular failure surfaces defined by the grid and radius method.

The stability of the near-surface weathered serpentinite bedrock was evaluated using several fully-specified, block-shaped slip surface planes at various depths below the slope surface. Each fully-specified slip surface plane was optimized to search for the lowest possible factor of safety. Optimization consists of dividing the slip surface plane into a number of straight line segments, the ends

of which are adjusted to search for the lowest possible factor of safety. The process is repeated for all the points located along the entire slip surface plane. Then, the longest line segment is subdivided into two equal length parts, with a new point inserted in the middle. This process is repeated until changes in the factor of safety are within tolerance or for a maximum of 2,000 trials. Once optimization is complete, Slope/W computes an axis point close to the approximate center of rotation of the sliding mass. The position of this axis point is not sensitive to the factor of safety calculations for Spencer's method.

The Contour phase presents the results of the analyses including the output shown in the figures in this appendix.

Infinite Slope Analyses:

The Infinite Slope Method was used for evaluation of shallow surface failures of frictional materials parallel to a slope. We used the following equation to determine factors of safety by the infinite slope method (where f is the internal angle of friction and b is the slope angle):

$$F = \frac{\tan f}{\tan b}$$

Results of the infinite slope calculations are shown on the figures generated from Slope/W in this appendix.

Defining Stability:

Both Slope/W and the Infinite Slope Method calculate a factor of safety, which is the ratio of the available resistance to sliding divided by the driving forces. The higher the factor of safety, the more stable the slope. Typically, a slope with a static factor of safety greater than 1.5 indicates a relatively stable slope. For short-term conditions, such as during construction, smaller factors of safety such as 1.3 are usually acceptable. Calculated factors of safety near 1.0 indicate that the slope may be on the verge of failure. Factors of safety well below 1.0 indicate that the slope analyzed would likely be unstable. For large earthquake loads, slope stability methods often yield factors of safety less than 1.0, indicating slope "failure." However, the amount of downward and lateral slope movement during the earthquake will depend on the severity of the earthquake and the static factor of safety of the slope.

Weathered Serpentinite Analyses:

As shown in Table 15, shear strength values were estimated for weathered serpentinite based on field and laboratory data. The strength values were assumed to increase with depth. As the stability analyses were being performed, it became evident that the field and laboratory for weathered serpentinite were relatively limited. Most of the deeper samples of serpentinite were from borings drilled on flat ground behind the bluffs near or beyond the existing batteries. Relatively few samples of serpentinite were collected from any significant depths on the face of the slopes. In most cases, the strength values from laboratory tests were inconsistent with sampling blow counts that suggested much higher strengths.

To evaluate the significance of low shear strengths that might be associated with weathered serpentinite, the slope face of Cross-Section D-D' of BBDA 2A was analyzed by non-circular methods using Slope/W. Serpentinite beneath the slope, except for the unweathered outcrop area at the top of the slope, was assumed to be weathered, with strengths increasing to a depth of 25 feet in accordance with the values in

Table 15. Below 25 feet, the serpentinite was assumed to have a strength equal to that of unweathered rock.

The weathered serpentinite analysis results are summarized on the following Figures D-A through D-J. The plotted results are for failure surfaces to different depths in weathered serpentinite, both under existing conditions and after waste fill is removed. The results indicate factors of safety ranging from 1.13 to 1.50 for existing conditions. Removal of waste fill resulted in increased factors of safety, ranging from 1.38 to 1.77. This is likely caused by a reduction in driving forces that occurs when the weight of the waste fill layer is removed.

The results of the weathered serpentinite analyses led to the conclusion that the serpentinite could be represented as unweathered rock in the slope stability analyses that focus on potential failures in the fill and native soils layers that blanket the slopes above the underlying serpentinite and mélange bedrock. We also concluded that it was not necessary to assign weathered strength values to serpentinite near or behind the existing batteries because these locations are well behind the slopes and would not be a factor in determining the critical (lowest factor of safety) failure surfaces. These assumptions greatly simplified these "full-slope" stability analyses (see below).

Full-Slope Stability Analyses:

Analyses of Cross-Sections A-A' through H-H' in BBDA-1, -1A, -2 and -2A are summarized in the following Figures D-1 through D-30. The conditions analyzed included:

- Existing conditions
- Waste fill removed
- Granular fill replaced
- Equipment and soil loads during construction.

APPENDIX E

DRAFT GEOTECHNICAL MEMORANDUM MATERIAL PROPERTIES

MACTEC

September 21, 2005

57255.005

Mr. George Ford
The Presidio Trust
1750 Lincoln Boulevard
San Francisco, CA 94129

Technical Memorandum
Geotechnical Material Properties for Slope Stability Analysis
Baker Beach Disturbed Areas 1, 1A, 2 and 2A
Presidio of San Francisco
San Francisco, California

Dear Mr. Ford:

MACTEC Engineering and Consulting, Inc. (MACTEC) is pleased to present this technical memorandum (memo) to the Presidio Trust (Trust) describing the proposed selection of geotechnical material properties to use in the slope stability analysis for Baker Beach Debris Areas (BBDAs) 1, 1A, 2, and 2A. During the meeting on April 5, 2005, with you, the National Park Service (NPS), and Dr. Ram Ramanujam of the California Department of Toxic Substances Control (DTSC), we discussed our general approach to selection of material properties for design. Because the material properties are such a critical element in the slope stability analyses, it was agreed to submit the results of the field and laboratory investigations, along with the recommended material properties and the rationale for the selection of these properties, for DTSC review before proceeding with the actual slope stability analysis.

The field investigation is nearing completion (summarized in Appendix A) in accordance with the Field Sampling Plan (FSP) dated January 27, 2005, and amended March 2, May 2, and September 8, 2005. You were provided with draft trench logs, test pit logs, boring logs, and laboratory test request forms, for your review in Data Packages #1 (April 25), #2 (May 24) and #3 (June 1). The geotechnical laboratory testing has recently been completed; however, further analytical laboratory testing is anticipated under the field investigation. For the purposes of geotechnical slope stability analysis, the completed laboratory and subsurface data has been used to update the geologic model to reflect our interpretation of the surface and subsurface conditions encountered during the field and laboratory investigation.

The purpose of this memo is to present the parameters for use in the slope stability analysis and describe how these parameters were selected. A geologic map of the site is presented, including cross sections showing the profiles that will be used in the slope stability analyses. Tables presenting the geotechnical data as well as the recommended material properties for analysis are also included.

Appendix A contains a short summary of the field exploration methods. Appendix B presents a summary of all of field and laboratory data. Appendix C presents an evaluation of the data, including data charts and recommended parameters for each slope stability analysis. Appendix D presents copies of Data Packages #1, #2, and #3.

BACKGROUND

Soil and Bedrock Units

Initially, we performed geologic mapping as a basis for interpreting the geology of the site and developing geologic model of the site to differentiate the surface soils and bedrock exposures. Following the subsequent subsurface investigation, the geologic map was updated to reflect the occurrence of the soil and bedrock units in the subsurface and integrate with the vertical dimension of the model (geologic cross-sections). Below are short descriptions of the geologic units present at the site.

Artificial Fill

Artificial fill covers much of the site and includes historic fill as well as waste fill as described below:

Historic Fill (**afh**) – This unit is classified as human-placed fill, which contains minor amounts of historic material that was placed in conjunction with the historic batteries. The fill in general contains wood planks and bricks associated with demolition of the earlier barbettes. The unit is broken down into the following sub units:

> **Afh** – This unit is classified as human-placed fill. This fill was placed at the time of construction of the batteries (either during the West Battery period, circa 1870, or the Endicott period, circa 1890 to 1905). In general the soil materials are both clayey and sandy with a general absence of gravel and cobbles.
>
> **Afh1** – In-place historic fill associated with the removal of the previous battery structures (barbettes or Battery West) and reworked later battery construction, if still considered to have significance as a cultural resource. In general, these materials are similar to Afh, but are now in a location different from their original placement, usually adjacent to the batteries.
>
> **Afh2** – Historic fill generated during the removal of the previous battery structures but is disturbed so that it no longer represents a historical or cultural resource. These materials are similar to Afh, but are sometimes mixed with other materials, reflecting their position and movement down the slope.

Waste Fill (**afw**) – This unit is classified as containing landfill (human-placed debris) resulting from construction demolition, household waste and vegetative (organic) waste. The chemical constituents do not necessarily contribute to the engineering properties but are important from the standpoint that the contaminated materials need to be removed, and thus affect the slope stability analysis.

Native Soils

Native Soils (**Qcol**) – These deposits represent in-place, native soils and unconsolidated sediments of various origins but with similar geotechnical characteristics, collectively mapped as (**Qcol**). These include Quaternary-age Colma formation soils, as well as colluvium and residual soils that represent residual weathered bedrock. In general, these materials consist of clays, sandy clays, and clayey sands, with varying amounts of gravels and occasional cobbles and boulders.

Landslide Deposits

Landslide deposits (**Qls**) – as shown on the geologic map, these occur in broad areas within the study area, but generally are not broadly present at the ground surface in the disturbed areas. In some locations, artificial fill overlies and conceals landslide deposits and colluvium.

Bedrock

Mélange (**KJm**) – occurs predominately on the lower portions of the slopes and consists of shale, mudstone, and varying large blocks of sandstone and siltstone in a sheared matrix. These materials are inherently unstable and subject to slope instability. It is pervasively sheared and deeply weathered with little soil development, as described in literature on the Franciscan Complex. The mélange materials rest in sheared contact with serpentinite.

Serpentinite (**sp**) – this ultramafic rock dominates the upper portion of the slopes, where locally it is as steep as vertical or slightly overhanging. The rock is massive with random shears and joints. Large landslide scarps occur south and north of the debris areas and support little vegetation. The sparse vegetation that does survive consists of native plants. The serpentinite weathers to a yellow brown silty or sandy clay.

LABORATORY PROGRAM

The purpose of our geotechnical laboratory program was to develop soil and rock strength parameters to supplement field classification of the site soils, and weathered rock for use in the slope stability analysis. The field investigation and laboratory test program were performed under the joint direction of a licensed geotechnical engineer and a certified engineering geologist.

Moisture and dry density (specific to determining geotechnical unit weights, and exclusive of moisture-only samples obtained for analytical analysis) testing was performed on 72% of the samples. In addition, the soil gradation (measured by sieve and hydrometer tests) and plasticity (measured by Atterberg limits tests) were tested at a frequency such that each soil type would be tested to confirm and calibrate the material classifications performed during field logging. In addition, samples that were disturbed during handling, contained large rock clusters, or that had crimped tubing were assigned moisture tests only or were not tested.

On samples that were deemed to be relatively undisturbed, a number of laboratory strength tests were performed. These included 39 unconfined compression (UC) tests, 25 unconsolidated-undrained (UU) triaxial shear tests, 4 consolidated-undrained (CU) triaxial shear tests, and 18 direct shear tests, distributed between the various geologic units.

SELECTION OF GEOTECHNICAL PARAMETERS

In selection of the appropriate geotechnical parameters for use in our slope stability analysis, consideration of the following sources of geotechnical or geologic information were made, including:

1. Historical records (e.g., historical limits of grading and waste dumping);
2. Site topography and geomorphology (e.g., angle of repose, areas of deposition or erosion);
3. Geologic mapping (e.g., characterization and areal extent of geologic units);
4. Results of the current and former subsurface exploration programs (*Dames and Moore, 1997*), to include test pits, trenches, and borings (e.g., vertical extent of geologic units, consistency or relative density);
5. Laboratory test results (index values, unit weights, material strengths); and
6. Literature correlations between index parameters (e.g., gradation, plasticity index, SPT penetration values) and typical ranges of material properties (e.g., unit weight, shear strength).[1]

In general, our approach for evaluation of materials to select the appropriate parameters for slope stability analysis proceeded as follows:

- Collection of the available historical records, published geologic maps, and site topographic map.
- Field mapping of the site to estimate the limits of fill and natural geologic units.
- Based on these sources of information, geotechnical and geologic staff made preliminary estimates of the depth of various fill and native soil units, then designed and performed a subsurface exploration program to collect data and samples of these materials.
- Based on an initial review of the subsurface field data, a laboratory test program was performed to confirm and/or calibrate field logging, and to provide quantitative information regarding moisture content, gradation, unit weight, plasticity, and shear strength.
- Once the data was collected, we proceeded with our evaluation as follows:
- Field and geotechnical data was summarized in a single spreadsheet (shown in Appendix B).
- For each general geologic unit, we developed plots of depth versus unit weight, undrained strength (based on UU, UC, and SPT blow counts), and internal friction angle (based on SPT blow counts). Some of these plots are discussed further and included in Appendix C. Based on these plots, a selection of recommended unit weights and strengths for each geologic unit was made. Each was checked to assure that it compared well with typical ranges for that material type and was reasonable and within the lower half of the range of reported results.
- Plotting of the results of the Direct Shear (DS) and CU tests, and comparison of these results with the preliminary values selected in the preceding step. These plots refined the selection of the friction angle for the effective stress analysis of granular materials. For clayey soils, effective

[1] Primary sources of published values include Duncan et al. 1989 (*Soil Strength and Slope Stability*); EPRI 1990 (*Manual on Estimating Soil Properties for Foundation Design*); and Hoek and Bray 1987 (*Rock Slope Engineering, 3rd Ed.*).

stress strengths were selected based on the results of the DS and CU tests as well as from published correlations with the measured plasticity indices.

- An examination of each geologic cross section, and the field and laboratory data for that respective cross section, to see that the recommended values appeared reasonable and appropriate. As discussed in Appendix C, in some locations strengths must be selected that provide a stable slope under current conditions (i.e., back-calculate to a factor of safety of unity in some of the steeper debris areas).
- In some cases, such as saturated clay samples, laboratory strength tests were considered to be the most reliable values available. In granular soils, the sample disturbance is usually so great that the most reliable strength values are derived from standard penetration resistance values. For bedrock, geotechnical and engineering geological observations were particularly important in selecting material strengths. In some highly weathered materials, laboratory strength tests can be particularly useful, whereas for more intact bedrock materials, blow counts may be useful. In some instances, the most meaningful information may be that derived from careful geological descriptions of material hardness, weathering, degree of cementation, fracture patterns, and other geologic parameters. Our final selection of recommended unit weights and strengths are based on the consideration of all the available data.

Table 1 — Recommended Material Properties

Material Description	Designation for Slope Stability Analyses	Total Unit Weight (pcf)	Short Term Analysis (Total Strength Parameters)		Long Term (Effective Strength Parameters)	
			Cohesion or Undrained Strength (c, psf)	Internal Friction Angle (ϕ, deg)	Cohesion or Undrained Strength (c', psf)	Internal Friction Angle (ϕ', deg)
Waste Fill[a]	**Afw**	125	0 700	36-39[a] 0	0 0	36-39[a] 30
Historic Fill (clayey)	**afh, afh1, afh2**	125	1000-2000[b]	0	0	32
Historic Fill (sandy)	**afh, afh1, afh2**	125	200	22	0	35
Landslide Deposit	**Qls**	120	0	39	0	39
Colma Fm/Native Soils (Qcol, clayey)	**Qcol1**, 0-10 ft	130	1200	0	0	30
	Qcol2, 10-20ft	130	1200-2500	0	0	30
	Qcol3, >20ft	130	2500	0	0	30
Colma Fm/Native Soils (Qcol, sandy)	**Qcol1** to **Qcol3**	130	150	30	0	30-35[b]
Bedrock, Melange units (KJm)	**KJm**	131	3000	0	3000	0
Resistant Bedrock, including serpentinite	**sp**	120	10,000	0	10,000	0
Weathered Bedrock, including serpentinite	**sp1**, 0-5ft	120	500	0	500	0
	sp2, 5-12ft	120	500-750	0	500-750	0
	sp3, 12-25ft	120	750-2000	0	750-2000	0
	sp4, >25ft, and in prominent cliff faces	130	2500	0	2500	0
Historic Fill (clayey)	**afh, afh1, afh2**	125	800-2000[b]	0	0	32

(a) Use the higher strengths (friction angle = 36-39 degrees) where demanded by slope geometry, as explained in Appendix C.

(b) Varies by location. In some locations, an internal friction angle of 36 to 38 degrees may be demanded by topography and geomorphology, as discussed in Appendix C.

Notes:
psf - pounds per square foot; pcf - pounds per cubic foot

The preceding table presents a summary of the recommended parameters for each geologic unit. Appendix C presents additional discussion.

- Note that the recommended values for native soils (**Qcol**) are broken down into three subunits as these materials exhibit different material strength properties, depending on depth of burial. Therefore, subunit designations (**Qcol1**, **Qcol2**, **Qcol3**) for use in the slope stability analysis have been included.
- Similarly, the observed serpentinite bedrock exhibits a significant degree of variability in strength, primarily depending on degree and depth of weathering, as observed in the weaker samples obtained during drilling and by the more competent bedrock in the prominent vertical outcrops. Therefore, these materials have been grouped into four subunits (**sp1**, **sp2**, **sp3**, **sp4**), correlated to depth as indicated in Table 1.

CLOSURE

We believe this memo provides information sufficient for your review. We suggest a meeting between the Trust, NPS, DTSC, and MACTEC be scheduled to discuss your review comments on this memorandum. If you have questions, please contact Mr. Bill Godwin at 707-793-3841, or Mr. Jim French at 510-628-3234.

Yours very truly,

MACTEC Engineering & Consulting, Inc.

(APPENDICES PROVIDED ON CD)

Appendix A of the Draft Geotechnical Memorandum provided a short summary of the exploration work performed for the 2005 investigation. A more detailed description of the Field Geotechnical Investigation, including the additional investigation near the GGBHTD parking lot, can be found in Section 2 of the Field Investigation Report text. Appendix A of the Geotechnical Memorandum will be included on CD.

Appendix A: SUMMARY OF FIELD GEOTECHNICAL EXPLORATION

The geotechnical exploration program was performed based on criteria and methods described in the project Field Sampling Plan (FSP) for Baker Beach Disturbed Areas 1, 1A, 2, and 2A, dated May 2, 2005.

The work was performed in three field phases:

1. Excavation of test pits using specialized equipment (Spyder, Model No. S2 "Kaiser Kuick Fuss") operated by AIS Construction. A total of 21 test pits were excavated and logged between depths of 3 to 22 feet below ground surface. Undisturbed (Shelby tube) and grab samples were obtained for laboratory testing. The Spyder was also used to drill and install 2 piezometers in BBDA-1 using hollow-stem auger methods (HSA).

2. Cultural Resource test trenches were excavated at the top of the bluffs by EERG utilizing conventional rubber-tired backhoe equipment. A total of 10 trenches were excavated and logged by MACTEC and URS personnel from between 3 and 14 feet below ground surface. No geotechnical samples were submitted for laboratory testing.

3. Soil Borings we drilled at the top of the bluffs by conventional HSA truck-mounted drill rigs (Gregg Drilling and Testing) and by custom limited access drilling equipment (8x8 rig, Clearheart Drilling). Drive (modified California and Standard Penetration Test [SPT]) samples and undisturbed (Shelby tube) samples were obtained in a total of 15 borings, ranging in depth between 6 and 26 feet below ground surface.

Appendix B of the Draft Geotechnical Memorandum provided a draft table of completed geotechnical laboratory test results performed for the 2005 investigation. An updated table is included in Appendix C-1 of the Field Geotechnical Investigation. Appendix B of the Geotechnical Memorandum will be included on CD.

Notes:

(1) Preceeding "05" on sample number (e.g. 05BBSB106(10.0)) indicates year.
Cultural resource trench samples (e.g. Trench 4 (4.5)) were not designated in the QAPP or FSP but instead were given field sample desciptions
(2) Refer to text and Plate 1 Geologic Map for description
(3) Unified Soil Classification System (USCS) designation
(4) Consistency/Relative Density based on EPRI, August 1990
(5) Recommended hammer and sample type converstion factor
(6) Hammer energy and sample type corrected blow count

Abbreviations Key:

HSA - Hollow Stem Auger
MC - Modified California Sampler
SPT - Standard Penetration Test Sampler
N-60 - Hammer energy and sample type corrected blow count
Phi Meyerhof - Internal friction angle (Phi) based on Meherhof table in EPRI, August 1990
Su = N/8 - Shear strength relationship based on N_60, EPRI, August 1990
Eff_Stress - Effective overburden stress
C_N - Overburden correction factor
N1,60 - N60 value corrected for overburden
Su - Undrained shear strength
DD - Dry Density
TD - Total or Wet Density
LL - Liquid Limit
PL - Plastic Limit
PI - Plasticity Index
tsf - tons (2000 pounds) per square feet
ksf - kips (l000 pounds) per square feet
psf - pouds per square feet

Notes:

(1) Preceeding "05" on sample number (e.g. 05BBSB106(10.0)) indicates year. Cultural resource trench samples (e.g. Trench 4 (4.5)) were not designated in the QAPP or FSP but instead were given field sample desciptions

(2) Refer to text and Plate 1 Geologic Map for description

(3) Unified Soil Classification System (USCS) designation

(4) Consistency/Relative Density based on EPRI, August 1990

(5) Recommended hammer and sample type converstion factor

(6) Hammer energy and sample type corrected blow count

Abbreviations Key:

HSA - Hollow Stem Auger
MC - Modified California Sampler
SPT - Standard Penetration Test Sampler
N-60 - Hammer energy and sample type corrected blow count
Phi Meyerhof - Internal friction angle (Phi) based on Meherhof table in EPRI, August 1990
Su = N/8 - Shear strength relationship based on N_60, EPRI, August 1990
Eff_Stress - Effective overburden stress
C_N - Overburden correction factor
N1,60 - N60 value corrected for overburden
Su - Undrained shear strength

DD - Dry Density
TD - Total or Wet Density
LL - Liquid Limit
PL - Plastic Limit
PI - Plasticity Index
tsf - tons (2000 pounds) per square feet
ksf - kips (l000 pounds) per square feet
psf - pouds per square feet

Notes:

(1) Preceeding "05" on sample number (e.g. 05BBSB106(10.0)) indicates year. Cultural resource trench samples (e.g. Trench 4 (4.5)) were not designated in the QAPP or FSP but instead were given field sample desciptions

(2) Refer to text and Plate 1 Geologic Map for description

(3) Unified Soil Classification System (USCS) designation

(4) Consistency/Relative Density based on EPRI, August 1990

(5) Recommended hammer and sample type converstion factor

(6) Hammer energy and sample type corrected blow count

Abbreviations Key:

HSA - Hollow Stem Auger
MC - Modified California Sampler
SPT - Standard Penetration Test Sampler
N-60 - Hammer energy and sample type corrected blow count
Phi Meyerhof - Internal friction angle (Phi) based on Meherhof table
Su = N/8 - Shear strength relationship based on N_60, EPRI, Augu
Eff_Stress - Effective overburden stress
C_N - Overburden correction factor
N1,60 - N60 value corrected for overburden
Su - Undrained shear strength

DD - Dry Density
TD - Total or Wet Density
LL - Liquid Limit
PL - Plastic Limit
PI - Plasticity Index
tsf - tons (2000 pounds) per square feet
ksf - kips (l000 pounds) per square feet
psf - pouds per square feet

APPENDIX C

ASSESSMENT OF GEOTECHNICAL PROPERTIES

Appendix C - Assessment of Soil and Rock Engineering Properties

For the purposes of slope stability analyses, for each geologic unit we developed plots of test results versus depth for moist unit weights and strengths. These plots are included in this Appendix. In some cases, strengths will be back-calculated based on existing slope configurations, and recommended strength for resistant serpentinite is based on topography/geomorphology and literature values.

The unit weights were developed based on moisture-density tests (MDs) on "minimally disturbed" samples of soil and rock. For cohesive soils, undrained strength was estimated based a combination of Unconsolidated-Undrained Triaxial Compression Tests (UUs; ASTM-D2850) and Unconfined Compression Strength Tests (UCs; ASTM-D2166), as well a correlation of shear strength based on the energy-corrected blow counts from driven samples. The shear strength for this correlation is related to the energy corrected blow count by dividing the energy-corrected blow count by a factor of 8. Internal friction angles for cohesionless soils were developed based on a published relationships of energy-corrected blow counts with corresponding internal friction ("phi") angles (Meyerhof, as presented in *Duncan, 2005*).

Based on these plots, we have developed total strength parameters that we believe will likely control the short-term slope stability conditions that are being assessed. Long-term stability analyses are based on effective strength parameters. Given the geologic and seismic setting of the project, seismic considerations for slope stability will be a factor. These factors are discussed further in the Technical Memorandum text. A discussion of how we estimated engineering properties follows for each of the geologic units:

- **Qls** (landslide deposit) – Several landslides were mapped within the Baker Beach bluffs, as shown on Figure 1. Along Cross Section A-A' in BBDA-1, and Cross Section D-D' in BBDA-2A, the slide deposits are within areas that will be analyzed for slope stability. No tests were performed on this material. However, based in the geomorphology of the slide in BBDA-1, it is clear that it is has recently been active and that it is currently lying at its approximate angle of repose. Since the slope inclination is currently about 39 degrees, it is clear that the soil must have an internal friction angle of at least 39 degrees, or an equivalent undrained strength. In BBDA-2A, the slope inclination is at about 38 degrees, so the internal friction angle must be at least 38 degrees or an equivalent undrained strength. Strengths for **Qls** will be selected based on a back-analysis for an existing safety factor of near or slightly above unity.
- **afw (**artificial fill, waste**) -** The moist unit weight was developed based on an average of the moist unit weights shown on Plot C-1. The afw soils appear to be predominantly cohesive and therefore an undrained strength value was estimated based on a grouping of strength data as shown on Plot C-2. Long-term effective stress strength parameters were selected based on the direct shear results shown on Plot C-3.

  It should be noted that along Cross Sections A-A' and C-C' in BBDA-1, and Cross Section B-B' in BBDA-2A, there are some areas where the existing slope steepness requires strength parameters greater than the values discussed above (which were based on field blow counts and laboratory strengths). As discussed above for slide deposits (**Qls**), in local areas the assumed strength will be increased to provide a current, pre-remedial grading, safety factor of about unity. This will be an internal friction angle of up to about 39 degrees (or an equivalent undrained strength) near the landslide discussed above (under **Qls**), and about 36 to 38 degrees in BBDA-2A.

- **afh (**artificial fill, historic**) -** The moist unit weight was developed based on an approximate average of the moist density as shown on the enclosed Plot C-4. The **afh** soils appear to be a mixture of granular and cohesive soils. For clayey soils, short term (undrained) strengths were selected based on a comparison of laboratory UU and Unconfined Compression (UC) tests and field blow counts, as shown on Plot C-5. Long-term strengths were based on effective strengths from the CU tests (Plot C-6) compared with typical values.

  For the granular or cohesionless soils, short-term (total stress) strengths were selected based primarily on total stress parameters from a laboratory CU test and laboratory DS tests (Plots C-6 and C-8, respectively), and compared with comparison of field blow counts (Plot C-7). Long-term strengths were based on a comparison of field blow counts, CU effective strengths, and DS tests (Plots C-7, C-6, and C-8, respectively).

- **Qcol (**Quaternary soils, mainly Colma formation, but may include residual soils**) -** The design moist unit weight was selected based on an approximate average of the moist density as shown on the enclosed Plot C-9. The **Qcol** soils appear to be predominantly cohesive soils and therefore short-term (undrained) strength values were estimated based on a grouping of strength data as shown on Plot C-10. Long-term strengths were selected based on a conservative evaluation of the DS test results and the effective stress parameters from the CU tests (Plots C-11 and C-12, respectively).

  For areas where **Qcol** is granular, short-term strengths were selected based on DS results (Plot C-11), and compared with field blow counts (Plot C-13). Long-term strengths were selected based on field blow counts compared with typical values and the DS results.

  It should be noted that along Cross Section B-B' in BBDA-2A, the existing slope steepness requires strength parameters greater than the values discussed above (which were based on field blow counts and laboratory strengths). As discussed above for slide deposits (**Qls**), along Section B-B' the assumed strength will be increased to provide a current, pre-remedial grading, safety factor of about unity. This will be an internal friction angle of up to about 36 to 38 degrees or an equivalent undrained strength.

- **KJm (**Cretaceous-Jurassic Melange**) -** The design moist unit weight was selected based on an approximate average of the moist density as shown on the enclosed Plot C-14. The KJm strength can be very conservatively assumed to have a lower bound associated with the strength of the clayey matrix supporting the more resistant rocky portions of the material. Therefore, strengths were selected based on a conservative grouping of strength data as shown on the enclosed Plot C-15. (It may be noted that several lower UC shear strength values were noted in this material. We interpret these lower values to represent pre-existing and discontinuous slickensiding resulting in unrepresentative strength values when tested in an unconfined condition.)

- **sp (**serpentinite**) -** The design moist unit weight was selected based on an approximate average of the moist unit weights shown on Plot C-16. On Plot C-16, showing all of the serpentinite unit weight data, it is apparent that at shallow depths (less than 12 feet) there are two distinct data clusters (A and B). The lighter unit weights were observed in samples from borings in the level area above Disturbed Area 1; these samples appear to represent more highly-weathered and friable rock materials that dilated when sampled, so that their measured densities are not thought to be representative of their insitu densities. The heavier unit weight samples were generally taken from areas other than Area 1 and were less weathered and more competent rock materials. Therefore, we recommend a single unit weight for both materials.

  Where the **sp** rock is resistant and less weathered, the strength should be modeled as a weak rock material. Hoek and Bray (1997) indicate that the unconfined compressive strength for very weak

rock may range from 10,000 to 250,000 tons per square foot. We recommend using the low end of this range for the analysis, i.e., use a shear strength of 10,000 kips per square foot.

Where the **sp** rock is deeply weathered, the strengths from the laboratory tests may be used. The weathered **sp** strength may be conservatively modeled as a cohesive soil. Shear strength values were estimated based on a comparison of laboratory UU and UC tests and field blow counts (Plot C-17), and laboratory DS results (Plot C-18). (It may be noted that several lower UC shear strength values were noted in this material. We interpret these lower values to represent pre-existing and discontinuous fractures resulting in unrepresentative strength values when tested in an unconfined condition.)

Appendix D of the Draft Geotechnical Memorandum provided color copies of raw field logs of test pits, test trenches and boring logs included in 3 separate data submittals. Also included were tables showing what laboratory test was assigned. The field logs have been updated and included in Appendices A, B and D and the testing program is summarized in a table in Appendix C1. Appendix D of the Geotechnical Memorandum will be included on CD.

Subject: Baker Beach 1, 2 Field Program
Interim Data Transmittal

Dear Bob:

This letter transmits preliminary test pit logs and tables summarizing samples collected to date in the Baker Beach 1 and 2 field sampling program. We are sending these along so that you and Ram Ramanujam can stay abreast of the progress of this work. The spider excavator and crew have performed very well on the steep slopes above Baker Beach and they've had good success in pushing Shelby tube samples.

This is a preliminary data submittal so we have not required MACTEC to provide a P.E. signature and stamp. This data will be included in final form in the report of the field sampling activities which will bear a P.E.'s stamp and signature.

Please call if you have questions.

Sincerely,

George A. Ford
The Presidio Trust

Baker Beach Geotechnical Investigation Debris Stability Data Package

Dear Mr. Ford:

Please find attached for your review a data package from our ongoing Baker Beach geotechnical program that constitutes our first geotechnical sample testing submittal. These samples were obtained from test pits as part of Debris Stability evaluation. The data package includes:

- Updated tables that show both proposed samples and testing (Table 2 of the most recent Field Sampling Plan) and the samples collected to date and submitted for geotech analysis;
- Preliminary test pit logs (including showing where the samples were collected)

Jim French, geotechnical engineer and Bill Godwin engineering geologist reviewed the draft test pit logs and the samples and assigned the geotechnical index and strength tests based on sample interval, sample recovery and condition and soil type. All samples intended for geotechnical testing were taken with thin-wall Shelby tubes unless noted on the table.

The tables and testing program are preliminary and may be revised as additional information is developed. Additional undisturbed samples will be obtained from soil borings and submitted for geotechnical laboratory analysis as part of our Battery and Staging Area evaluations in May.

Please contact Jim French (510) 628-3234 or Bill Godwin (707) 793-3841 if you have any questions.

Yours very truly,

MACTEC Engineering and Consulting, Inc.

Michael Jacobvitz
Senior Principal Hydrogeologist

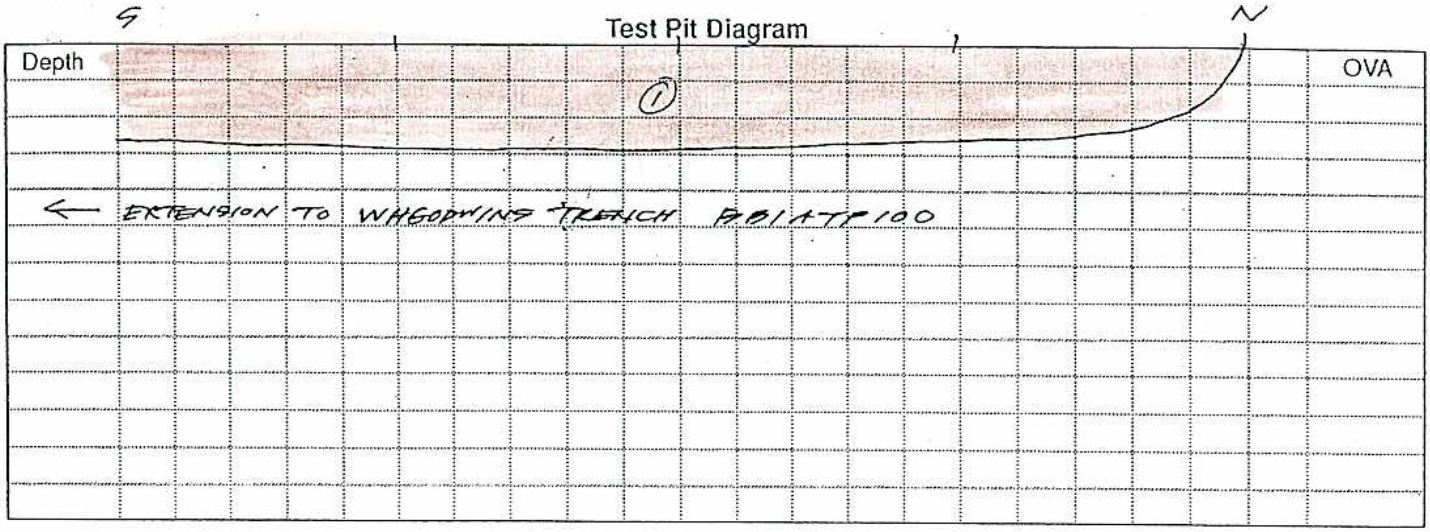
Test Pit Diagram



Test Pit Descriptions

Description:

(A) medium to mottled grey w/ brown SILTY SAND (SM), med dense, damp, with clods of yellowish brown clay; abundant roots deeply within serpentinite cobbles (Fill) contains asphalt fragments

(B) medium grey SILTY SAND to SAND w/ silt (SP-SM), med. dense, uniformly fine grained, abundant serpentinite bldrs to cobbles. Contains asphalt clods to 3" ø, ~~10% by volume~~ (~~Fill?~~) 30% by vol (6"–3' ø) v. minor consistency of dense sand (Colma?)

(C) Serpentinite, hard, weak to friable, crushed, slightly wthd. fracture surfaces w/ clay coatings.

Sample Numbers: TP101-2.5 Mod-cal (45 blows/4"); TP101-7.0 sampled in sidewall (pushed)

☒ Grab samples - G1 roofing matl.; G-2 sand. (Environmental)
